v. 36

Jan - Dec. 1946

c. 1

American Journal of Public Health

and THE NATION'S HEALTH

Index to Volume 36, 1946

How to Use the INDEX

This is an Index to all the reading matter in the JOURNAL. It is essentially a title and author Index, although occasional subject headings are provided.

Articles, committee reports, and editorials are listed alphabetically according to the key words in the title, with many cross-references.

Editorials are indexed under "Editorials" as well as alphabetically under the key words in the title.

News notes and fillers are indexed under "News from the Field." This section should be searched as supplemental to the title index.

Matters pertaining to the Association are indexed under "American Public Health Association."

Book reviews are indexed under "Books and Reports."

Obituaries are indexed under "Death Notices."

tion of a major division of the health agency and who is largely responsible for the technical content of her program.

The report has been widely used by (1) colleges and universities training nutritionists and those arranging public health nutrition curricula; (2) administrators of civil service and merit systems; (3) employers selecting nutritionists, and (4) individuals preparing themselves for service in this field or arranging additional preparation for themselves or their staff.

Although the recommendations have proved helpful, their limitations have become increasingly evident. The subcommittee is agreed that the time has come to act on the implied promise in the footnote to the original report: "This report like all other statements of the Association on professional and technical qualifications in public health, is subject to periodic revision in order that it may be kept abreast of the best thought." The recommendations that follow cover the principal types of nutrition positions in the field of public health at the present time. It is impracticable to insist that all present incumbents comply with these requirements; they are recommended for application to candidates applying for appointment.

II. STATEMENT OF FUNCTIONS

A. The nutritionist in a public health agency is a qualified professionally trained person who directs or carries on a program of activities dealing with the application of the scientific knowledge of nutrition to the promotion of positive health, the prevention of ill health, and the dietary control of disease. The nutrition program of a health agency is directed toward strengthening the service that the agency is rendering in determining the health status of the population served, in dealing with the causes of ill health, in caring for

the sick entrusted to its care, and in promoting well-being among groups and individuals through better food practices.

The function of a highly organized nutrition service of a large health agency will include most, if not all, of the following activities. In smaller health agencies the range of functions will be narrower.

1. Organizing and carrying out a program to:

a. Control dietary deficiency diseases through determining their prevalence and distribution and, if they are found to constitute a public health problem of some magnitude, by conducting or participating in clinics for their diagnosis and treatment.

b. Prevent dietary deficiencies and promote health through encouraging wise production or selection and proper processing, preparation, and use of the foods necessary for optimum nutrition. Such programs frequently call for cooperation between the health agency and agencies and organizations in the fields of agriculture, education, welfare, industry, medicine, nursing, and dentistry.

2. Studies and surveys:

a. On prevailing food practices of the population of a given area or of special groups, such as school, children, industrial workers.

b. On cost, availability, and use of foods needed to furnish an adequate dietary, these to be used as guides for setting up nutrition programs.

c. On the nutritional status with respect to certain factors of the population of a given area or special groups, such as residents of a home for the aged.

d. On the effect on nutritional status of modifications in the diet.

e. On the effectiveness of nutrition programs in improving food supplies and practices.

3. Preparation and assembling of materials for nutrition education and reviewing the nutrition content of all educational materials prepared or distributed by the agency.

4. Professional education. Participation in the field training of public

health students and in the orientation and in-service training of the staff of the health agency.

a. Imparting to public health workers and allied personnel a working knowledge of human food needs, nutritive values of foods, and methods of improving nutritional status in coöperation with whatever specialized personnel in nutrition may be available in the area served.

b. Participation in the pre-service and in-service training of nutritionists and of workers in related fields, such as educators, social workers, managers of food service in schools, child care centers, or institutions.

5. Consultation services for workers in health or allied agencies in regard to nutritional needs and dietary practices of individuals, families, institutional and industrial groups, or a cross-section of the population of a given area, with the object of planning ways of meeting these needs and improving practices within the resources—actual or potential—of the individuals or groups under consideration.

6. Individual and group instruction of adults and children on food, nutrition, and budgeting, in connection with health conferences or clinics or with the educational or service program of the health agency in schools or the agency's program of community education.

7. Compilation and, if necessary, preparation of nutritionally adequate food market orders, menu plans, and recipes, adjusted to various cost levels, to racial, religious, or regional food practices, and to individuals in unusual circumstances, such as night shift workers or persons living outside of family groups. Similar service for therapeutic and other special diets recommended by physicians.

8. Coöperation with welfare agencies in formulating budget standards for food to meet the nutritive needs of individuals, family groups, and institutions, and in calculating the cost of

standard food budgets at prevailing prices.

9. Inter-agency relationships. Bringing about closer relationships between the health agency and other agencies carrying on educational, service, or research programs in nutrition.

10. Coördination of nutrition programs. Participation in the organization and continuing activity of coördinating councils in the field of nutrition and health and in the organization of communities for unified effort toward the improvement of nutritional status and the maintenance of a satisfactory level of nutrition once attained.

B. Classification of different grades

The nutrition positions in health agencies may be grouped into 3 grades: (1) The director of a nutrition service in a health agency with responsibility for a staff of workers; (2) the nutritionist who acts primarily as a consultant and neither has responsibility for a staff of workers nor receives close technical supervision; and (3) the staff nutritionist working under close technical supervision from the director of a nutrition service. These grades are described in somewhat more detail in connection with the statements of education and experience under III and IV.

III AND IV. BROAD EDUCATIONAL BACKGROUND (UNDERGRADUATE) AND GRADUATE EDUCATION

A. For a director of a nutrition service in a health agency with responsibility for a staff of workers. The essential qualifications for the incumbent of this position are broad grasp of the science of human nutrition, knowledge of public health administration, and administrative ability. The director cannot be expert in every aspect of public health nutrition but should be able to recruit and supervise a staff that together will possess competence in all the major

fields. Directors of nutrition services in health agencies may have acquired the necessary qualifications through any one of several backgrounds of education and experience but these backgrounds will have certain elements in common, as indicated in the following paragraphs:

1. Education. Human nutrition should be the subject of major interest. A director of nutrition service should have at least one year of full-time graduate academic credit in addition to the undergraduate academic training leading to a baccalaureate degree or its equivalent in pre-medical training. The combination should be so chosen as to qualify the student for participation as a nutritionist in the public health field.

Colleges and universities offer graduate training in public health nutrition in professional schools of public health or in postgraduate programs in nutrition based on undergraduate preparation in home economics. The content and extent of graduate study required to supply this training will vary according to the type of undergraduate preparation, the interval since such work was completed, the relevancy of any work experience, and the scope of the program directed.

a. The *undergraduate course of study* leading most immediately to preparation for public health nutrition is that qualifying the student for a baccalaureate degree with a major in foods and nutrition as offered in a course in home economics. Such a curriculum includes as a requirement basic courses in chemistry (including physiological or biochemistry), physiology, bacteriology, the social sciences (economics, sociology, and psychology), human nutrition, food study (selection, marketing, preparation), and educational methods. Electives often include introductory courses in statistics, child development, journalism, and public speaking.

b. Students whose undergraduate major has been in the biological sciences, social sciences, education, or pre-medical studies, will need to supplement such preparation with the required courses listed above.

c. The minimum of one year of *full-time graduate academic study* should feature advanced courses in human nutrition, and together with the undergraduate study should give a working knowledge of: methods and techniques of nutrition investigations and dietary studies, child hygiene and development, public health administration, health education, principles of supervision, community organization and resources, and social case work.

d. A course in hospital dietetics accredited by the American Dietetic Association is a desirable addition to other types of graduate preparation but is substitutable only in so far as it carries academic credit in courses essential for public health nutrition. Completion of the requirements for a degree as doctor of medicine or doctor of philosophy in biochemistry constitutes adequate educational preparation for the field of public health nutrition when the students have had full courses for academic credit in human nutrition and its applications in the field of public health.

e. Field work in a health agency carrying on a nutrition program under the supervision of a qualified nutritionist should be provided preferably at the graduate level.

2. Experience *

a. Minimum of 4 years of successful, paid experience as a nutritionist in a health agency or a welfare agency carrying on a nutrition and health program. At least one year must have involved responsibility as a supervisor of both professional and clerical staff or as a consultant, or

b. Two years in the above plus 4 years in any one of the following positions or any combination of them:

(1) Therapeutic or teaching hospital dietitian

(2) Physician engaged in clinical medicine, teaching of medical students, research, or public health

(3) Dietitian or nutritionist employed by a food clinic, child development center, school system, nutrition council or committee

(4) Research worker in human nutrition

(5) Teacher of foods and nutrition in a school, college, or university, or adult education program

* Candidate should have had part of training and experience indicated within 4 years of the time of application.

Blood and Blood Derivatives— A New Public Health Field*

CHARLES A. JANEWAY, M.D.

*Harvard Medical School and School of Public Health, and the
Infants' and Children's Hospitals, Boston, Mass.*

UNTIL recent years, blood transfusion was not considered a matter of great concern to public health officials. A few private organizations strove to improve the technical aspects of transfusion, while others, in some cases allied with public health agencies, attempted to fill the needs of contagious disease hospitals and private physicians by collecting and distributing convalescent serum. Shortly before the war, a number of hospitals had established blood banks, and a few of them had even begun to distribute plasma and blood to neighboring institutions. Certain pharmaceutical laboratories likewise began the preparation and distribution of blood serum and plasma in liquid or dried form, thus providing these valuable therapeutic agents to physicians everywhere. The war has greatly accelerated the trend toward the widespread use of blood and blood derivatives—partly because a blood procurement, processing, and distribution program, in which the American Red Cross, the pharmaceutical laboratories,

and the armed forces have coöperated, has made blood, freely donated by the American people, available in great quantities to physicians treating our wounded in every corner of the globe; partly because the OCD has stimulated the development of blood and plasma banks in many of the hospitals of the country; and partly because research in this field has expanded the possible clinical uses of blood and its derivatives. The American public has been educated to blood donation, and the public has become conscious of the fact that anybody who needs blood or its derivatives should not be deprived of something which the armed forces have demonstrated can be made universally available.

The sheer number of transfusions given annually is enough to command attention from public health authorities, but there are more compelling reasons: (1) protection of the public from disease transmitted by blood and its derivatives; (2) provision to the public of blood products for the prevention of communicable disease; (3) distribution of blood and blood products

* Special Review Article prepared at the request of the Editorial Board.

for use in the treatment of disease. These reasons in order indicate an expanding conception of the functions of a health department. The first acknowledges its customary responsibility for the protection of the public from transmissible disease whenever there are accepted methods of control. The second, the provision of agents for the control of transmissible disease, is a logical extension of the first. The third, however, represents an excursion of public health agencies into the practice of medicine and therefore demands justification.

1. *The transmission of disease by blood and its derivatives*—The fact that certain diseases can be transmitted by the transfusion of blood has been recognized for a good many years. Its importance lies in the fact that these diseases are frequently serious, are often unrecognizable in the donor, and have become more widespread in our population as a result of the war.

a. *Syphilis*—The application of sensitive "exclusion" tests for syphilis to the serum of prospective donors has reduced the incidence of transfusion syphilis. However, it is possible to transmit syphilis by transfusion from a donor in the primary stage of the disease when the serologic test may still be negative.¹ Hence the introduction of laws requiring the physician to certify that a donor is free of transmissible disease, presumably as the result of a careful physical examination. Such laws, although worthy in purpose, are rather unworkable, and reliance should be placed on the use of bank blood, since blood held in the refrigerator for at least three days is unlikely to transmit the disease.² While other spirochetal diseases and certain bacterial infections may also be transmitted by blood, these should be ruled out by such simple procedures as temperature taking and brief questioning of the donor.

b. *Malaria*—The transmission of ma-

laria by transfusion is well authenticated. In Massachusetts, Rubinstein has shown that transfusion malaria has been more common than the mosquito-born disease in recent years.³ Although the tertian and aestivo-autumnal forms may be transmitted by the blood of recently recovered patients, quartan malaria is the usual type, since the parasites may persist for thirty years or more and the donor may not be aware of ever having had malaria. It seems likely that donors from the veterans' groups who have been in the endemic malarious zones, particularly the Mediterranean area, will have to be excluded as donors for whole blood and their blood converted to dried plasma or plasma fractions in order to obviate this risk in the post-war period.

c. *Homologous serum jaundice*—A vexing problem has been created by the realization that blood or plasma from an apparently healthy person may produce severe hepatitis with jaundice in the recipient several months later. The causative agent is probably a virus, which may circulate in the donor's blood for considerable periods without recognizable symptoms, and which is able to survive long periods of storage and to pass ordinary bacteriological filters. The importance of this disease which had been recognized for some time by British workers⁴ was brought home with full force when epidemics of jaundice broke out in troops of the United States⁵ and British armies⁶ as well as in the civil population of Brazil⁷ who had received yellow fever vaccine stabilized with a small amount of human serum.

Although the agent of hepatitis may be transmitted in whole blood, the statistical chances of its transmission are greatly increased by the pooling procedures used in making plasma. The disease has a long incubation period, varying from 60 to 180 days, its pathology appears to be much the same

as that of epidemic hepatitis (catarrhal jaundice) with acute yellow atrophy in fatal cases⁸ and evidence that in non-fatal cases the process ultimately results in complete restitution of normal liver architecture,⁹ while its prognosis is perhaps somewhat more serious. Whether or not it is the same disease modified by a different portal of entry or a different disease cannot yet be stated categorically. Methods for destroying the agent in whole blood and plasma which are applicable on a large scale have not been found. At the start of the plasma fractionation program to be discussed later, it was feared that the incidence of serum jaundice might be extremely high because of the size of the pools of plasma used (200–10,000 donors per pool) and the fact that the methods used would probably not damage such a hardy virus, but experience with the products of plasma fractionation has so far failed to substantiate this fear.

d. *The transmission of antigens and anaphylactic antibodies by transfusion*—Following the ingestion of food, small amounts of unmodified protein may pass through the intestinal mucosa and enter the circulation. Foreign proteins may be injected into donors in the form of various types of vaccines and sera. For these reasons it is important that donors be used in the fasting condition and that those donors who have had recent inoculations should be excluded, since the transfusion of blood containing small amounts of foreign protein into a highly sensitive subject may result in severe anaphylactic symptoms. The passive transfer of hypersensitiveness of the anaphylactic type by virtue of the presence of antibodies in the donor's blood may also occur. Thus the use of very highly allergic donors or of those who have recently had injections of serum or vaccine such as rabies vaccine is also to be deprecated unless their blood is to

be used in plasma fractionation where it will be pooled with so many other bloods that antigens or antibodies will be diluted sufficiently to render them innocuous.

e. *The Rh factor in medicine*—Recent studies upon the importance of the Rh factor and the production of anti-Rh agglutinins as the result of pregnancy or multiple transfusions do not need to be elaborated here.¹⁰ However, the fact that such antibodies may lead to fatal transfusion reactions and to erythroblastosis foetalis in the new-born indicates that facilities for determining the Rh status of donors and recipients must be available wherever transfusions of whole blood are used in obstetrical patients, in the new-born, or in patients who have received multiple transfusions.

This rather brief outline of some of the forms of disease, besides reactions due to incompatibility or pyrogens, which may result from the transfusion of blood or its products, indicates that strict control is necessary. Of the conditions mentioned, most are preventable by proper selection of donors and by good technique, but the problem of serum jaundice remains an enigma which needs solution. The possibility of disease transmission emphasizes both the need for proper regulations concerning blood donors and the value of centralized blood collection in a few depots where it is possible to maintain technical staffs who are competent to screen donors intelligently and to direct their blood into the different channels in which it may be used with safety. Moreover, it emphasizes the need for the provision of laboratory facilities and standardized reagents for blood grouping so that this essential determination can be made with accuracy.

2. *Use of blood in the prevention of disease*—The use of convalescent serum, normal serum, or placental extract in the control of measles has become a standard procedure in medical prac-

tice.¹¹ The recent demonstration that the gamma globulin fraction of normal human plasma is even more satisfactory will be discussed below. This fraction is also effective in the prevention of epidemic hepatitis. Since these two diseases are widespread and endanger the health of the public, there is every reason for health departments to provide these materials to physicians.

3. *Distribution of blood and blood derivatives for the treatment of disease—*

The assumption of responsibility by public health authorities for any phase of the care of patients with illnesses other than those which menace the health of the community is an extension of their functions which will be subjected to criticism. In this instance, its justification would appear to lie in the social and economic spheres. Blood and its derivatives have come to be recognized as essential adjuncts to good medical care, and unless they can be distributed to physicians under public auspices many patients will be deprived of them, at least until the cost of all blood derivatives is reduced very considerably and better facilities for distribution become available than at present.

THE PLACE OF BLOOD AND ITS DERIVATIVES IN MODERN MEDICINE AND SURGERY

It is now possible to sketch the main outlines of a program for the most economical and efficient use of human blood in the treatment and prevention of disease based on methods which have been developed in the past few years for separating some of its many physiological components. In the following section an attempt will be made to review briefly the clinical uses of blood and its derivatives and some of the improvements in techniques which underlie them.

1. *Whole blood*—The war has demonstrated the crucial importance of whole

blood transfusion in repairing the results of hemorrhage, a major factor in the pathogenesis of wound shock. Although plasma and albumin have played an extremely useful rôle in saving lives simply because they could be transported and stored so easily, it has become quite clear that when a large amount of blood is lost, its replacement with plasma protein solution results in the development of anemia, which in turn will have untoward physiological effects unless corrected.¹² The widespread use of whole blood in recent campaigns has been made possible by two principal factors: rapid transportation by air and improvement in the anti-coagulant solution used. Refrigerated blood has been flown across both Atlantic and Pacific oceans after its collection in this country so rapidly that it could be used for a considerable period after its arrival on the fighting fronts. This would never have been feasible if the conventional sodium citrate solution had been used as an anti-coagulant. The life of stored blood under optimal conditions with this solution is scarcely more than five days. On the other hand, solutions have been devised which will increase the life of blood on storage to three or four weeks. The solution which has gained widest use is acid citrate dextrose (ACD) solution¹³ which differs from sodium citrate in the presence of a small amount of glucose and the use of a mixture of sodium citrate and citric acid in order to produce a final pH of approximately 7, *i.e.*, slightly acid to the normal blood pH. These solutions, by prolonging the life of stored blood, diminish the danger of transmission of syphilis. Whether improved preservation of the red cell will increase the time of survival of the malarial parasite in whole blood remains to be determined. ACD solution is superior to the modified Rous-Turner solution recommended by DeGowin¹⁴ simply because the amount

of fluid used is very much smaller, thus conserving transportation space and reducing the size of the infusion necessary to produce a given physiological effect.

Many proposals have been made to use whole blood in emergencies without cross-matching. Witebsky and his colleagues have shown that purified blood group substances A and B can be added to group O blood to neutralize its anti-A and anti-B isoagglutinins.¹⁵ Such neutralized O blood may be used in emergencies without preliminary cross-matching except when there is reason to fear reactions dependent upon the Rh factor, *i.e.*, in obstetrical patients, the new-born, and in recipients of previous transfusions. However, the fact that plasma or albumin can be used for the emergency treatment of shock with almost complete freedom from reactions suggests that they might well be used to tide a patient over until his blood group is determined and compatible blood can be administered.

2. *Resuspended red blood cells*—Upon centrifugation, the first division of blood into its functional components can be made, *i.e.*, into cells and plasma. After removal of the plasma, the packed cells may be resuspended and used for the transfusion of patients in whom there is a deficiency of red cells but an adequate supply of plasma protein. This applies particularly to those forms of anemia for which transfusion provides the only available method of therapy, namely leukemia, aplastic anemia, and the hemolytic group of anemias. If whole blood can be kept for periods up to thirty days, there seems little reason why it should not be possible to keep resuspended cells for a similar period. Although red cells resuspended in saline have been safely administered to many patients, the useful life of the cell in saline is only about five days.^{16, 17} Corn syrup has been proposed as a resuspension me-

dium,¹⁸ and many investigations are now in progress which should ultimately indicate what type of solution is optimal for this purpose. If resuspended cells can be given a dating period of a month from the time of collection, it will mean that their distribution from blood depots to any part of the United States should be entirely feasible and that their safety could be controlled by insisting upon a sufficient period of storage to assure the destruction of agents such as *Treponema pallidum* or the *plasmodia* of malaria and to allow the completion of sterility tests. Since resuspended cells can be administered in concentrated suspensions and in larger amounts than whole blood without overloading the circulation, it is possible to shorten the period of treatment for patients with severe anemia.

3. *Plasma*—Plasma will undoubtedly be preferred in this country to serum, which has been extensively used in the British Commonwealth.¹⁹ Although the latter may be filtered with ease to insure sterility, its preparation involves the loss of fibrinogen, and the red cells, occluded in the clot, cannot be used for resuspension. Plasma can be prepared in a number of forms, each of which has advantages for particular purposes. Liquid plasma, kept at room temperature to prevent the precipitation of certain proteins and lipoids will supply the colloid osmotic effect of plasma.²⁰ However, on storage at room temperature its labile components deteriorate and thus it is not effective for supplying prothrombin, fibrinogen, or hemophilic globulin.²¹ If plasma is kept in the frozen state, it can be preserved for long periods of time unchanged and, when thawed rapidly, may be used to supply these various labile proteins. Its principal disadvantages are the expense of refrigeration equipment and the time necessary to thaw the material. Dried plasma is fairly well preserved but requires expensive

facilities for its preparation and must be reconstituted with water for use.²² The value of plasma, (1) as a substitute for whole blood in the treatment of hemorrhage, (2) as the agent of choice in replacing the plasma lost in burns or peritoneal irritation, or (3) as a means of providing preformed protein for injection into hypoproteinemic patients with acute illnesses, has been amply demonstrated in the last few years.^{23, 24, 25} To what extent plasma will be used in the future, however, remains to be determined since the further separation of plasma into its component parts makes it possible to administer in comparatively pure form many of the individual plasma proteins mediating different physiological functions.

4. Plasma fractions—

a. *The process of plasma fractionation*—Plasma and whole blood have in the past been given for many conditions in which the patient suffered from a deficiency of only one particular component of plasma. Thus, in hemophilia, there is a marked prolongation of clotting time due to a deficiency in hemophilic blood of one of the normal plasma globulins.²⁶ The transfusion of fresh plasma containing this protein results in a prompt fall of clotting time to normal just as does the addition of a small amount of fresh plasma to hemophilic blood *in vitro*.²⁷ The transfusion of 100 or 200 ml. of fresh plasma at frequent intervals to hemophilic patients at times of hemorrhage or when essential surgical procedures are carried out is time-consuming and wasteful, since the actual amounts of the particular protein needed by the patient are very small. If this anti-hemophilic factor were made available in relatively pure form, the material could be given in a very small injection, thus simplifying treatment for both doctor and patient, and much larger amounts of material could be administered when necessary to severe cases without the unpleasant

side effects which may go with massive transfusions of blood or plasma. It is this type of reasoning which lies behind the program of plasma fractionation.

Methods which make it possible to separate plasma proteins on a large scale into relatively pure fractions have been developed by Cohn, Strong, Oncley, Hughes and Armstrong and their associates.²⁸ They depend primarily upon the precipitation of different plasma protein fractions by varying concentrations of alcohol at low temperatures with control of the temperature, hydrogen ion concentration, ionic strength, and protein concentration of the solution. Such a system with five different variables makes it possible to define optimal conditions for the separation of the many plasma proteins. Moreover, the use of alcohol substitutes for the clumsy process of dialysis the desiccation of precipitates from the frozen state with evaporation of the small amounts of alcohol and water carried down with them, leaving the proteins as dry powders which may be kept until needed for final packaging. This program is still in the phase of development, and, although a number of products have been derived from the basic fractions, there are other products with potential clinical uses which have not yet been brought to the point of adequate purification and clinical trial. The more therapeutic agents that can be produced from a given amount of plasma, the more economical such a process becomes both from the standpoint of the costs of production and the better utilization of human blood.

This system of plasma fractionation* which has been developed with blood

* A series of papers describing the chemical characteristics of the products of plasma fractionation and the physiological, pathological, immunological, and clinical studies made with them will be found in a single number of the *Journal of Clinical Investigation*, to which the reader is referred for details.²⁹ Pertinent publications not included in this series will be referred to in the text.

collected by the American Red Cross as a result of a group of studies carried on under various auspices, but principally under contracts, recommended by the Committee on Medical Research, with the Office of Scientific Research and Development, and with the coöperation of the U. S. Navy, gives rise to five primary fractions. Fraction I contains most of the fibrinogen and serves as the source of its various derivatives. The next fraction, Fraction II + III, is a combined fraction, containing alpha, beta, and gamma globulins. It is separated by subfractionation into a gamma globulin fraction containing most of the antibodies of the plasma, a fraction containing prothrombin, a fraction in which the isohemagglutinins are concentrated provided the plasma pool is made up from bloods of one group only, and a lipoprotein fraction. Fraction IV contains alpha and beta globulins, some of them lipoproteins and others water-soluble and containing but little lipid. Fraction V contains most of the albumin of the plasma. Fraction VI contains a very small amount of protein and consists mainly of salts and soluble material not precipitated during the process of fractionation. In so far as possible, the whole process has been designed to separate the various protein components of plasma so as to preserve the functional integrity of all.³⁰ The stability of these fractions varies markedly, and consequently this goal has not always been perfectly realized. However, as knowledge has accumulated, it has been possible to improve the process progressively in such a way as to carry the separation of the various components to a point where they may be preserved in stable form for future use.

With this very brief outline of the major fractions, we shall turn to a consideration of the applications which have been found for the final products prepared from them.

(1) *Products of fibrinogen and thrombin*—The proteins known to be concerned with blood coagulation are fibrinogen, prothrombin, anti-hemophilic globulin, and fibrinolysin. The processing of fibrinogen and prothrombin to stable and satisfactory products for clinical use is now well under way and considerable amounts of material have been delivered for use by the armed forces.

(a) *Fibrin foam and thrombin*—Fibrin foam consists of a coagulum of fibrinogen and thrombin which is beaten with air to attain a spongy consistency and which can then be cut into pieces of the desired size, desiccated and sterilized by heat. In this form it is stable, dry, and brittle. Before use, it is soaked in a solution of reconstituted thrombin which renders it flexible and permeates it, so that when it is applied to a bleeding area, the blood welling up into the foam is promptly coagulated and thus the foam becomes incorporated in a clot which extends into it from the bleeding surface. The great advantage of fibrin foam is that it consists of human proteins, is absorbable, and can be left *in situ*, without subsequent reaction. It has proved extremely valuable as a hemostatic agent in surgery, particularly in neurosurgery. Thrombin is prepared by conversion of the prothrombin separated from Fraction II + III, and is then dried from the frozen state since it is unstable in solution. Fibrinogen itself is likewise unstable but can also be kept when dried from the frozen state. Powdered fibrinogen and thrombin have been studied as aids in various surgical procedures, for example as a means of forming a coagulum around a renal stone so it may be removed without crumbling or as a physiological glue for the application of skin grafts.

(b) *Fibrin film*—By various manipulations, fibrinogen may be converted into a number of types of sub-

stances, the properties of which will depend upon the conditions under which the clot is formed and its subsequent chemical, mechanical, and thermal treatment. Fibrin film is an elastic, tough, semi-transparent membrane, which has been found quite useful as a substitute for the dura mater covering the brain when this has been removed at operation or as a result of trauma. Here the film is slowly absorbed and replaced by connective tissues without inciting the formation of adhesions between the brain and its coverings.³¹

(c) *Antihemophilic globulin*—Fraction I has been found to contain the greatest concentration of antihemophilic activity of any of the plasma fractions.³² Studies of the usefulness of Fraction I in repairing the coagulation defect of hemophilia upon intravenous or intramuscular injection have been made, and indicate that injections of from 200–400 mg. of Fraction I are as effective as 100–200 ml. of plasma in bringing the coagulation time back to normal.^{33, 34} Further clinical studies in this disease are indicated, when sufficient Fraction I becomes available over and above the needs of the armed forces for fibrin foam and film.

(2) "*Gamma*" *globulin (immune serum globulin)*—The gamma globulin fraction of plasma contains all the antibodies against infectious agents normally present in pooled plasma for which clinical or laboratory tests have been made. The degree of concentration of these antibodies parallels quite closely the degree to which gamma globulin is concentrated from the plasma, as determined chemically. Thus present preparations for the American Red Cross and the armed forces consist of a 16.5 per cent solution of protein, of which more than 95 per cent is gamma globulin. This represents an approximately 25-fold concentration of this protein over its concentration in plasma and it has been found that antibodies

such as diphtheria antitoxin, scarlatinal antitoxin, complement-fixing and mouse-protective antibodies to influenza A virus, and agglutinins for the H antigen of the typhoid bacillus are concentrated from 15 to 25-fold. Antibody studies on gamma globulin prepared from bloods collected in different areas of the country at different times have revealed a few interesting variations.³⁵ Thus antibodies to influenza A approximately doubled after the epidemic of the winter of 1943–1944. Diphtheria antitoxin titers are lower in California and relatively high in the Southwest. Early in the program of plasma fractionation, Robinson³⁶ suggested that such a globulin fraction of pooled adult plasma might be useful in the prevention and attenuation of measles. This has turned out to be the case and numerous publications indicate that human gamma globulin provides a safe and reliable agent for either the prevention or modification of measles, depending upon the dosage used.^{37, 38, 39} Its principal advantages are its availability, safety, and uniformity. Recently Stokes and Neeff have demonstrated that gamma globulin is very potent as an agent for the prevention of epidemic hepatitis.⁴⁰ Because of the usefulness of this material in the prevention of measles and the fact that more gamma globulin became available as a result of the plasma fractionation program than was necessary to meet the requirements of the armed forces, the American Red Cross has arranged for its distribution to the public through public health agencies.⁴¹

It is obvious that from the standpoint of the public interest, it would be extremely unwise to use globulin for the prevention of measles or hepatitis every time that a patient was exposed to one of these diseases, since this would merely result in the gradual development of a very large susceptible population. On the other hand it is

important to be able to prevent measles in such institutions as hospitals or in particular individuals, and gamma globulin has proved excellent for this purpose. Moreover, the evidence indicates that modification of measles after known exposure by the use of small doses of gamma globulin results in a diminution of those complications which make measles a serious disease. Adequate statistical evidence must be brought forward, when sufficient data accumulate, to prove, as is generally believed, that such mild attacks of measles establish a permanent immunity.

Unfortunately not every communicable disease can be prevented by the administration of gamma globulin. The results so far have been rather unsatisfactory where it has been administered to patients exposed either to mumps or chicken pox. A recent study in New York State, using gamma globulin as a source of poliomyelitis antibody in very large doses, has confirmed the previous findings with convalescent serum that administration of antibody during the pre-paralytic stage of the disease has no effect on its outcome.⁴²

There is a field for further investigation in the concentration of antibodies from convalescent sera, particularly in the case of scarlet fever and mumps, where there is reason to believe that the globulin fraction might be useful in either prevention or treatment. McGuinness demonstrated that the administration of gamma globulin from convalescent mumps plasma on the first day of mumps parotitis appeared to diminish the incidence of orchitis, whereas globulin from normal plasma failed to do so.⁴³ Convalescent plasma provides as satisfactory a source of albumin, thrombin, fibrinogen and other plasma proteins as normal plasma and therefore in a blood procurement program of the future, its collection and fractionation so that the antibodies can be preserved until needed may be very

worth while. Another field in which only a start has been made is in the production of human hyperimmune plasma. Hyperimmunization of humans has been used for the development of serum against *Hemophilus pertussis*, the etiologic agent of whooping cough. Such serum appears to have definite value in passive protection against whooping cough and probable value in the treatment of the disease.⁴⁴ It has been subjected to fractionation, and hyperimmune pertussis globulin is now commercially available.

(3) *Isohemagglutinins* — Since proper blood grouping is essential for the safe use of whole blood transfusions, it is important to have potent, standardized reagents for this purpose. By pooling plasmas of one group only at the start of the fractionation process, it is possible to obtain from Fraction II + III very satisfactory isohemagglutinin preparations. It has recently been shown that, although good A (anti-B) globulin can be obtained from Group A bloods, better B (anti-A) globulin is obtained from pooled O bloods absorbed with B cells than from B bloods.⁴⁵ Since O and A donors are found in approximately equal number in the population and the B donors provide the right amount of B cells for absorption of the anti-B agglutinins from O blood, this greatly simplifies isohemagglutinin preparation.

(4) *Human serum albumin* — The albumin fraction of plasma makes up about 55 per cent of the total plasma proteins and is largely responsible for their osmotic effect. Albumin is not only more potent osmotically but less viscous in solution, more soluble, and more stable than most of the plasma globulins. Thus, when separated, it is possible to dispense it in a 25 per cent solution which has the viscosity of whole blood with a hematocrit of 50. Moreover, albumin is a water-soluble protein and thus may be dissolved in

water or any of the commonly used intravenous solutions. One hundred ml. of a 25 per cent albumin solution has an osmotic effect equivalent to 500 ml. of citrated plasma, and provides a concentrated protein solution which is stable enough to be transported for long distances and stored at ordinary temperatures and which, when properly prepared, gives an extremely low incidence of reactions on intravenous injection. Because it does not have to be reconstituted and can be injected rapidly, it is the agent of choice for emergency administration in cases of shock. The compactness of albumin would make it extremely convenient for a practising physician to carry with him, just as it is convenient for front-line use in the armed forces. Albumin may be combined with any desired amount of parenteral fluid, and a 5 per cent solution of albumin in saline or glucose is approximately isosmotic and isotonic with human plasma. Thus albumin might easily replace plasma since it supplies the osmotic effect needed in shock and also the particular plasma protein which is deficient in most cases of hypoproteinemia. In the treatment of hypoproteinemia, the fact that the albumin can be given in a small volume of fluid containing very little sodium ion makes it far superior to plasma, in which there is a much larger amount of sodium present, which may aggravate the edema in certain cases.^{46, 47} The small volume and safety of albumin is a great convenience in pediatric practice. To date, albumin has had comparatively little civilian use for the simple reason that all that is being produced is required by the armed forces.

(5) *Other fractions of plasma*—

No mention has been made of clinical uses for most of the alpha and beta globulins, among which are found the lipoproteins associated with the transport of fat as well as certain enzymes

and hormones which circulate in small amounts. Clinical and chemical studies are under way to investigate the possible applications of this remaining group of plasma proteins.

This brief resumé will serve to show the manifold uses for blood and its products in the clinic. It is clear that considerable further experience will be necessary before the most effective scheme for the utilization of blood can be worked out in detail. It is conceivable that whole blood, resuspended cells, and plasma fractions may ultimately provide all the therapeutic agents needed, but at present there are many who feel that plasma should be included. Whereas whole blood has certain very important clinical uses, in many other instances it should be replaced by the use of resuspended cells on the one hand or plasma or its fractions on the other. Moreover, the development of plasma fractionation provides many new therapeutic agents for general use such as albumins, gamma globulin, and fibrin foam with thrombin, which were not previously available. An important by-product of the plasma fractionation program is the introduction into the biologics industry of new methods for the separation of proteins—methods which are applicable to the purification of animal sera, vaccines, and tissue extracts. The remainder of this review will be concerned with a discussion of some of the possible methods for making blood and its derivatives generally available on an equitable basis.

ORGANIZATION OF A BLOOD PROGRAM

The administrative problems involved in a comprehensive blood program may be divided into several phases—those of procurement, processing, and distribution. Let us assume that the objective is to provide the optimal amount of blood and its derivatives to all who need them, in the safest possible form, and

at the minimum public expense. There are numerous ways of attaining this objective in each phase of the program and it is probable that in different parts of the country, with their differing facilities and needs, different methods may prove best. It is to be hoped that various methods will be tried, so that it will be possible to make comparisons between them. The integrated program carried out for the armed forces during the war in this country as well as in the British Commonwealth has been responsible for a tremendous expansion of facilities for the procurement and processing of blood, and has provided invaluable experience, which should be carefully studied by all those charged with the responsibility of developing blood programs for the civil population in the future.⁴⁸ Several states have already launched programs or have laid plans to do so. Both Michigan⁴⁹ and North Dakota⁵⁰ have begun to collect, process, and distribute plasma on a state-wide basis, while Massachusetts⁵¹ is planning a program for the collection of blood, processing of plasma and plasma fractions, and distribution of the products to physicians of the state.

The rôle of public health authorities in such programs may vary from a minimum of setting up proper regulations and standards to a maximum of control and management of every phase of the program. The National Institute of Health already assures the safety of commercially available blood derivatives through control of all biological products produced for interstate sale.

1. *Blood procurement*—There are two methods of obtaining human blood, either by appeal to donors to give their blood free, or by purchase in the open market. Both methods become simpler as the public becomes educated to blood donation. There should be little difficulty in maintaining an adequate flow of blood on a voluntary basis after

the war is over. In London, a volunteer blood transfusion service under the Red Cross has been successfully operated since 1921. Hospital blood banks have been able to keep on hand adequate supplies collected from relatives and friends of patients in many cities where the Red Cross Blood Donor Service was recruiting large numbers of donors at the same time. The motives of self-interest and community spirit can be utilized. In Michigan, for example, plasma is distributed in any community on a basis of blood contributed, a certain percentage of the total amount collected in a given community being returned to it as plasma, and a smaller amount being kept in a central pool for emergency use in any part of the state where it might be needed. Hospital blood banks operate on the same principle, but on a smaller scale. The use of paid donors would be utterly impossible for any broad blood program if donors had to be paid at the previous conventional rate of \$5 per 100 ml. of blood. However, if the fees paid to donors can be reduced to very much smaller sums, then the use of paid donors becomes somewhat more feasible from an economic standpoint.

The procurement of blood might be carried out either by the Red Cross, which has done such a magnificent job in the collection of blood for the armed forces, by professional teams under the health department as in Michigan, through established hospital blood banks, or by a commercial laboratory which might contract to supply local needs through the use of paid donors. The National Red Cross has ruled that local chapters may collaborate in the procurement of blood with health agencies if they so desire, provided certain principles are adhered to, among which are: voluntary blood donations only, technical responsibility wholly in the hands of a reliable medical or health agency, a unified program of volunteer

blood donor service in any one community to serve all acceptable hospitals and licensed physicians, and no charge for blood or blood derivatives to be made to physicians, hospitals, clinics, or patients.⁵² There is much to be said for a unified blood procurement program for a particular area, from the standpoint of economy, technical competence of the staff, and safety of both donor and recipient.⁵³ By steering blood from donors in various categories into whole blood, plasma, or plasma fractionation, the available donors can be utilized most efficiently with the least chance for transmission of disease.

2. *Blood processing*—The processing of blood to liquid or frozen plasma is being carried out quite successfully in many hospital blood banks in the United States today. On the other hand, the production of dried plasma or plasma fractions involves a large initial expenditure for equipment and a technical staff which it would not be feasible for any one hospital to maintain unless they were processing blood derivatives for a large area. This could be done most satisfactorily and economically either by the commercial laboratories which have had so much experience with the process during the war or by the laboratories of some of the larger state health departments. The actual cost of the plasma fractionation process is remarkably low, and the more products that can be derived from plasma, the less expensive each of them becomes. Once the initial outlay for equipment is taken care of, the costs of plasma fractionation should be considerably less than those required for the procurement and distribution of blood, particularly if the donor must be paid.

3. *Distribution*—In no phase of a blood program would it seem to be so important for a public agency to play a rôle as in the field of distribution. The cost of the plasma or albumin re-

quired for the treatment of a single patient with hypoproteinemia or of the resuspended cells required by a patient with aplastic anemia, for example, no matter what the method of blood procurement or processing, will exceed the capacity to pay of most patients with these conditions. Experience has shown that in those hospitals with blood and plasma banks, much larger amounts of blood and plasma are used than in hospitals not so equipped, indicating that the needs exceed present civilian supplies. It is conceivable that the most economical way to take care of this problem would be to have all blood derivatives prepared by the commercial laboratories, with the cost of their provision to the medically indigent borne by public welfare agencies. On the other hand, the health department might procure and distribute at public expense the various blood derivatives discussed above. Commercial distribution on a competitive basis involves rather high costs compared to distribution by public agencies. Whether or not the public agency acquires the finished products from the commercial laboratories, or procures the blood and pays a commercial laboratory for the processing, or carries out the whole program on its own is of little consequence and will probably vary from one locality to another.

SUMMARY

An attempt has been made to review the various aspects of the use of blood and its derivatives in the prevention and treatment of disease from the standpoint of those concerned with the public health. The latter have an important regulatory function in seeing to it that the public is protected from disease transmitted or produced by blood and blood derivatives, and that those blood products required for the control of communicable disease should be made readily available. Moreover, there is

much to be said for the distribution of blood and its derivatives for use in the treatment of disease at public expense since this should result in an equitable system of distribution of these essential therapeutic agents regardless of the capacity of the patient to pay. Some of the manifold uses for blood and its various derivatives — resuspended cells, plasma, the products of plasma fractionation—have been reviewed, and brief mention has been made of the administrative mechanisms that may be brought into play in order to provide an adequate supply of blood and blood derivatives to the civilian population in this country.

Typhoid Vaccine Studies X

The Suitability of Vi Antigen as an Auxiliary Immunogen for Typhoid Vaccine

Progress Report

MAJOR GEORGE F. LUIPPOLD, S.N.C.*

Division of Typhoid Research, Army Medical School, Washington, D. C.

THE extraction of an active anti-typhoid immunogenic fraction (Vi antigen) from a coliform organism designated by Kauffmann as "*S. coli* 5396/38"¹ was announced last year in a preliminary report by Luippold.² Since this announcement, studies have been made on the stability of the Vi extract under a variety of conditions, on its immunogenic activity when combined with bacterial vaccines, and on its toxicity for laboratory animals and for man. Also, methods of preparation and standardization have been simplified and improved. These factors are of preliminary importance when considering the usefulness of any substance as an auxiliary immunogen for typhoid vaccine. The only remaining property of practical importance (should Vi extract qualify in the others cited above) is its effectiveness in man. This will be considered in a separate report to be submitted at a later date. The present communication deals with the preparation, stability, and toxicity of the Vi extract, and the feasibility of employing it to reinforce a bacterial vaccine.

EXPERIMENTAL

A brief review of the work leading up

to publication of the preliminary report cited above is desirable in order to introduce the studies referred to in the title of this paper.

THE EFFECTIVENESS OF VI EXTRACT AS AN ANTITYPHOID IMMUNOGEN

Upon extraction of this substance, the first step was to establish its position among previously recommended preparations of typhoid antigens in respect to immunogenic potency. As stated in the preliminary report, the product used for experimentation was a dispersion of the dried material obtained by precipitating out with alcohol or acetone those substances on *S. coli* 5396/38 soluble in dilute (1 per cent) HCl. Thus, the Vi extract could be compared on a dry-weight basis with two preparations of antigenic fractions of the typhoid bacillus, one of which was derived from a tryptic digest (Antigen 1), the other from an autolysate (Antigen 2). These products were titrated for immunogenic potency simultaneously with the Vi extract in a series of four individual active-immunization tests in mice. Details and results of these titrations have been included in Table 1.

It is apparent, from these results, that per unit weight of material, the Vi extract is somewhat superior to conventionally prepared antigenic fractions of the typhoid bacillus, when mice immu-

nized with these substances are challenged by infective (invasive) doses of *E. typhosa*.

EFFECTIVENESS OF VI EXTRACT IN THE PRESENCE OF PARATYPHOID ORGANISMS

Although there has never been any intention of replacing typhoid organisms in TAB vaccine with the Vi extract, the antityphoid potency of a product in which such a substitution had been made was determined, merely to detect any interference with the activity of the extract which might be exerted by the paratyphoid organisms.

Accordingly, a product consisting of 250 million of each of the paratyphoid A and B organisms and 0.01 mg. of dried Vi extract per ml. was prepared to represent ViAB. This was matched against TAB vaccine containing the

same numbers of paratyphoid organisms and 1,000 million typhoid bacilli per ml.—the stock TAB vaccine in current use. Appropriate controls were included, as will be noted in Table 2 where details and results of this comparison have been recorded.

It will be seen that the Vi extract retained its activity in the presence of paratyphoid organisms, and that ViAB was quite as effective an antityphoid agent as was TAB vaccine. However, it is not implied by this that typhoid organisms could adversely be replaced by the Vi extract, in-practice. All typhoid immunogens should be present in a vaccine. Vi antigen is considered as merely a supplementary substance which can be added advantageously to the other antigens (contained in the cells) of the typhoid bacillus.

0.000005	4/4	3/4	4/4	...

COMPARATIVE IMMUNOGENIC POTENCY OF TAB AND TAB VI

Having established the freedom of activity of Vi extract in the presence of paratyphoid organisms, it was only natural to choose TAB vaccine as the first product to be fortified with the extract. Although the TAB vaccine used by the U. S. Army has given a good account of itself, there has never been any assumption on our part that it could not be improved. The addition of Vi extract appeared to be a simple and direct method of improving this product which has already been tested in the field, without altering any of its original components.

Evidence of such enhancement was sought as follows: To 50 ml. of stock TAB vaccine was added 0.5 mg. of the Vi extract. This TABVi was titrated for antityphoid potency against the same lot of TAB in a series of three individual tests. Details and results have been recorded in Table 3.

The antityphoid potency of TAB vaccine was increased approximately 10-fold by the addition of 2,000 Typhoid Immunogenic Units³ (in the form of Vi extract) per ml. of vaccine. Experimentally, at least, fortification of TAB vaccine with Vi extract is both feasible and demonstrably effective.

NOTE: The foregoing is the definitive work on which was based the suggestion in the preliminary report that Vi extract be used as a fortifying agent for TAB vaccine. The work reported below was done subsequently in order to determine the suitability of Vi extract for such use, from the standpoints of preparation, standardization, stability, and toxicity.

PREPARATION OF VI EXTRACT

The original announcement of this Vi extract² stated that the substance was extracted from V-form organisms with dilute solutions of HCl, precipitated out with acetone, and recovered as a light-brown powder. It has since been found, however, that the cleared (centrifugalized) digest of organisms in HCl is a preferable form with which to work, and such a product is recommended, prepared as described below.

The culture designated *S. coli* 5396/38 is grown to produce a maximum predominance of V-form colonies. This is accomplished by colony selection and by incubation at room temperature (20° C.-25° C.). In our experience, we have been unable to obtain a 100 per cent V-form growth, there being invariably a sprinkling (about 1 per cent) of the W-form present.

When the culture has become predominantly V-form, massive transplants

are made to infusion-agar plates and incubated at room temperature for 24 hours. The growth is suspended in distilled water, and the organisms are extracted with acetone, then dried in a desiccator.

One gram of dried organisms is then added to 100 ml. of a 1 per cent solution of HCl (1 part 36 per cent HCl to 99 parts distilled water). Solution of available substances is allowed to take place for 1 day at room temperature, with shaking at frequent intervals. The mixture is then cleared by centrifuga-

tion at high speed (3,000 r.p.m.). Various extraction periods have been tried, from 1 hour to 10 days; however, apparently nothing is gained by extraction for more than 1 day (see Table 4). An even shorter period may prove to be adequate.

From this basic HCl extract, cleared by centrifugation, the material can be further purified by precipitation with alcohol or acetone, then dried, weighed, and resuspended in distilled water. However, resuspension is not easily accomplished and a completely satisfac-

		0.000005	6/6	6/6

tory dispersion has thus far not been obtained. We prefer to work with the cleared supernate of the raw HCl digest obtained as described above, after neutralization with NaOH. In this form, the Vi extract is a concentrated water-clear solution which does not precipitate out upon standing and is otherwise (chemically) quite stable. An interesting fact in regard to the relative stability of the raw HCl solution and the neutralized product was demonstrated in potency tests of these preparations after various periods of storage in the refrigerator. Contrary to expectations, the raw HCl solution was less stable in respect to both physical and immunogenic properties. It showed considerable precipitate and it had lost much of its immunizing potency, whereas the neutralized sample of the same substance was unchanged physically and retained its original immunogenicity. Comparative determinations for immunogenic potency of raw and neutralized samples of the same basic preparations of Vi extract have been recorded in Table 5. These indicate that early neutralization of a newly prepared product is advisable.

The neutralized solution of Vi antigen may be standardized biologically (determination of its TIU value)³ or by determining the dry weight of organic substance present—which is represented by the difference in weight between the solids present in a measured amount of solution after desiccation in a jar at room temperature, and the residual weight after heating at 500° C. in a crucible. For our purposes, we have found that a determination of the TIU value of the substance is preferable; for, in so doing, we can add a certain number of TIU's to each unit volume of vaccine with assurance of the extent of effective increase in immunogenic potency.

This neutralized product, prepared as described above, was used in the follow-

ing reported experiments to determine the stability of its immunogenic properties.

METHOD OF TITRATING IMMUNOGENIC POTENCY

The method of titrating all substances reported in this paper is essentially that described in a previous publication.³ Briefly, it consists of injecting intraperitoneally 0.5 ml. amounts of serial 1:10 dilutions of the substance (or of a dispersion of the dried material in distilled water) into respective groups of mice, followed 6 or 7 days later by a challenging dose of typhoid organisms suspended in 5 per cent mucin and intraperitoneally administered.

STABILITY OF VI EXTRACT

The first question which naturally arises is in regard to the stability of Vi extract in the presence of preservatives such as phenol, tricresol, and formaldehyde. One or another of these substances would likely be present in any bacterial vaccine, and its potential destructive effect would have to be reckoned with.

Another important point, closely linked with the effect of preservatives on Vi extract, is storage—storage of Vi extract as a dispersion in distilled water and as a component of typhoid vaccine, in a refrigerator and in the warmth of living conditions, to represent ideal and adverse situations, respectively.

Still another question arises, concerning the physical stability of Vi extract: If it were made a component of typhoid vaccine, would it remain in the suspending fluid as an independent substance, or would it become adsorbed to the bacterial cells? In either case, certain theoretical advantages would be gained while others would be lost. This question is chiefly of academic interest, but the answer should be available.

TABLE 6

STABILITY IN THE PRESENCE OF PHENOL,
TRICRESOL, AND FORMALDEHYDE

Preparations titrated in this experiment consisted of respective portions of V-Ex-7 to which had been added 0.5 per cent phenol, 0.25 per cent tricresol, and 0.2 per cent formalin. These materials were stored in the refrigerator, and titrated at various intervals for immunogenic potency. Details and

results of these titrations have been recorded in Table 6. The results indicate that there has been little if any significant change in the immunogenic potency of V-Ex-7 after 9 months of exposure, at about 5° C., to 0.5 per cent phenol, 0.25 per cent tricresol, or 0.2 per cent formalin. In fact, the preparations of Vi extract containing these preservatives maintained their potency

quite as well as the control material—which itself showed little change during the period of observation.

STABILITY TO HEAT

1. Extreme Heat

Autoclave (124° C.)—It is not anticipated that any biological product would be subjected to such mistreatment as autoclaving, but this information was sought merely as supplementary data on the properties of the Vi extract. The results of titrations of an autoclaved preparation have been recorded in Table 7. They indicate that considerable damage was done to the immunizing fraction of Vi extract. Any other result would have been, contrary to our present concept of the chemical identity of immunogenic substances.

Boiling Water Bath (100° C.)—It is neither to be expected that biologicals will be exposed for any length of time to this temperature, but a breakdown of substances by heating to 100° C. for a short period would probably indicate deterioration over longer periods at a lower temperature. The Vi extract, represented in three forms, was immersed in a boiling water-bath for 30 minutes: (1) as the raw HCl solution, (2) as the neutralized solution, and (3) as the neutralized solution to which

0.5 per cent of phenol had been added. The results of titrations for immunogenic potency (recorded in Table 8) indicate that no significant changes were produced in any of these preparations by heating at 100° C. for 30 minutes.

2. Moderate Heat

Incubator (at 37.5° C.)—It is very likely that vaccines, particularly en route to their destination, will be subjected to this temperature for greater or lesser periods of time. The test to determine the effect of such exposure employed the Vi extract as a component of TAB vaccine (TABVi), approximately 2,000 TIU having been added per ml. of TAB. The results of titrations for immunogenic potency have been recorded in Table 9. They indicate that, at this temperature, deterioration of the antityphoid component of TAB vaccine is more evident than in the case of TABVi, the explanation probably being that Vi extract is less affected and that an excess of it in the dilutions of TABVi used compensates for the destruction of the antityphoid factor of the typhoid organisms.

Room Temperature (22° C.–26° C.)—It is expected that vaccines will be exposed for some time to ordinary room temperature, en route to their destina-

TABLE 9

	1 week	0/8	2/8	6/8	8/8
	2 weeks	0/8	5/8	8/8	8/8

tion and while being used. Except through gross negligence, however, the total period of such exposure for any particular bottle of vaccine should not exceed 1 month. The relative keeping properties of TAB vaccine and phenolized Vi extract were determined, the conditions of storage (on shelf in office during June-July) being identical, while the materials were titrated simultaneously. The results of these titrations have been recorded in Table 10. They demonstrate that, stored at room temperature, the Vi extract is at least as stable as TAB vaccine.

STABILITY OF VI EXTRACT IN TAB VACCINE

Physical Stability—The physical stability of Vi extract in TAB vaccine—that is, its dependence upon the bacterial cells (adsorption) or its independence from cells (acting as a true solution) was briefly studied as a matter of interest.

The supernates of TAB vaccine, and of TAB to which Vi extract had been added 2 months previously (TABVi) were titrated, with adequate controls, for immunogenic potency. Details and results of these titrations have been

recorded in Table 11. From these results, it appears that Vi extract, mixed with TAB vaccine, maintains essentially an independent existence in the suspending fluid. Some adsorption to bacterial cells does seem to take place, but to a very slight extent and at a very slow rate.

Immunogenic Stability—This topic was discussed above under the heading of "Stability to Heat—Moderate Heat—Incubator at 37.5° C.," with results entered in Table 9.

TOXICITY OF VI EXTRACT

As would be expected, Vi extract is a toxic substance. The critical question is: To what extent would the addition of an effective concentration of Vi extract to TAB vaccine increase the frequency and severity of clinical reactions?

In testing this substance for toxicity in laboratory animals, it was found that although 16 to 18 gm. mice tolerated an intraperitoneal injection of 0.5 ml. (approximately 10,000 TIU), 3 kg. rabbits were invariably killed by this dose when intravenously administered. With such a wide divergence in species susceptibility, there was no way of predicting the toxicity of Vi extract for man except to employ man as the experimental animal.

Accordingly, the author was injected with trial amounts to explore their effect in a somewhat sensitized individual. From the slight local reactions which resulted, and the absence of any systemic manifestation, it was estimated that 200 TIU would be comfortably tolerated by less sensitized persons. Eleven volunteers were thereupon injected intradermally with 200 TIU contained in 0.1 ml. of the preparation. This amount is the immunogenic equivalent of 1.0 ml. of monovalent typhoid vaccine.

In all cases, there was some degree of erythema surrounding the site of injection, with slight to moderate tenderness in the central area, at the end of the first 24 hour period. The hyperemic areas ranged in diameter from 2.5 cm. to 5.0 cm.—averaging less than 10 sq. cm.² The intensity and extensiveness of these reactions were appreciably less than those generally produced by 0.1 ml. of typhoid or TAB vaccine. In all instances, objective and subjective symptoms rapidly subsided during the second 24 hour period. Neither lymphadenitis nor systemic reactions of any description were experienced by the participants.

DISCUSSION AND RECOMMENDATIONS

Vi extract, prepared as described in

this paper, lends itself well to use as an auxiliary immunizing substance for typhoid or TAB vaccine. It is easily prepared and standardized; it is chemically and physically stable in the presence of commonly used preservatives, and it is appreciably less toxic than an immunogenically equivalent amount of typhoid vaccine. Added in small amounts to TAB vaccine, Vi extract increases significantly the antityphoid potency over that possessed by the vaccine alone, as measured by active immunization tests in mice.

It is realized that active mouse protection bears a problematical relationship to the protection of man against infection, and that these experiments must ultimately be confirmed in man. In our experience, however, those agents which were the more potent as measured by active immunization tests in mice proved to be the more active in man as measured by serum protection tests. This still falls short of field tests, but it is the best method of laboratory evaluation available.

Despite the feasibility of fortifying TAB vaccine with Vi extract and the consequent gain in antityphoid immunogenicity, the addition of this extract to TAB vaccine of the present bacterial content and mandatory dosage is not recommended. Because of the occasional incapacitating reaction and the more frequent annoying reactions resulting from administration of the prescribed dosage of the currently prepared TAB vaccine, it is believed that any manipulation of the vaccine should be toward a product (or dosage) equally effective immunologically but less provocative of clinical reactions. The addition of Vi extract to the presently prepared TAB vaccine, without any modification of dosage, could, conceivably, aggravate an already undesirable feature of typhoid-paratyphoid vaccination.

Among the alternative procedures.

there are two that warrant investigation: One is to reduce the "T" component of TAB vaccine and add Vi extract in a compensatory measure; the other is to add Vi extract to the present TAB product, and reduce the dosage. Since an investigation of the effect and effectiveness of a reduced dosage of TAB vaccine (three 0.5 ml. doses) is already in progress here, it has been decided to await the findings of this investigation before taking any steps toward fortifying TAB vaccine with the Vi extract.

Another project involving the use of Vi extract to be opened in the near future is its use in combination with immunogenic fractions of the typhoid bacillus—such as Wakeman's polysaccharide⁴ or Morgan's "purified antigen,"⁵ for the purpose of augmenting these products with the important Vi fraction which is destroyed or diminished in their preparation.

SUMMARY

The extraction of Vi antigen from *S. coli* 5396/38 organisms with 1 per cent HCl is described.

The Vi extract was found to be immunogenically more potent than conventionally prepared antigenic fractions of the typhoid bacillus when titrated by active immunization tests in mice.

The Vi extract was found to be stable in the presence of preservatives commonly used for biologicals (phenol, tricresol, and formaldehyde) and under conditions of handling and storage usually applied to biologicals.

In a few experimental subjects, an amount of Vi extract immunogenically equivalent to 1 ml. of typhoid vaccine (200 TIU) administered intradermally, was found to produce a mild local reaction with no accompanying systemic manifestations.

The addition of Vi extract to TAB vaccine under present conditions of bacterial content and prescribed dosage is

not recommended because of the potential increase in frequency and severity of clinical reactions following the use of such a combination. A study of the effect and effectiveness of reduced dosage of TAB vaccine is now in progress, and a decision of how Vi extract will be used is pending the outcome of this study.

It is also planned to combine Vi extract with conventionally prepared immunogenic fractions of the typhoid bacillus, and to compare this combination with a bacterial vaccine in respect

to immunological responses and clinical reactions.

Proposed Diabetic Survey

A coöperative project is being conducted in Philadelphia to x-ray the chests of persons in the city having diabetes. The cost of the survey will be borne by the Philadelphia Tuberculosis and Health Association. The appointment of necessary committees is under the guidance of the Philadelphia County medical committees on diabetes and tuberculosis, together with the X-Ray Survey Committee of the Philadelphia Tuberculosis and Health Association.

At the meeting September 24 at the Philadelphia County Medical Society, physicians interested in diabetes and tuberculosis discussed the various aspects of the survey, bringing out that it would be invaluable in shedding light on

certain concepts long held regarding the response of diabetic patients to tuberculosis. It was further brought out that a mass survey might confirm or refute the concepts that hilar and basal sites are more frequently involved in tuberculous diabetic patients. The recording of simple data relevant to nutritional status might illumine the question as to whether or not nutritional status is one of the major factors in the increased susceptibility of diabetic patients to tuberculosis. It is proposed to divide the city into districts, installing a mobile x-ray unit in suitably located central hospitals for the x-ray examination of the diabetic patients in the vicinity and of non-diabetic outpatient controls.

Age and Sex Variations in the Prevalence and Onset of Diabetes Mellitus

MORTIMER SPIEGELMAN AND HERBERT H. MARKS

Statistical Bureau, Metropolitan Life Insurance Company, New York, N. Y.

IN this paper, there are presented estimates of the sex and age distribution of the existing diabetic population in the United States, of the new diabetics expected each year, and of those in the population who may eventually become diabetic.

PREVALENCE

In preparing the estimates which form the basis for this paper, use was made of the findings of the National Health Survey in regard to diabetes prevalence. This survey was conducted

United States. Morbid conditions were recorded by trained enumerators as they were reported by a member of the household. Wherever possible, an effort was made to confirm the diagnoses by referring to the physician in attendance. Through the courtesy of George St. J. Perrott, Chief, Division of Public Health Methods, National Institute of Health, there have been made available unpublished data regarding diabetes prevalence which form the basis for this paper.² These data are shown in Table 1.

during the winter of 1935-1936 under the auspices of the U. S. Public Health Service.¹ It covered 2,500,000 white and colored persons living in 700,000 households in 83 cities and was so planned as to constitute a sample representative of the general urban population of the

Quality of the data: It is possible to obtain some light on the quality of the data by comparing them with another experience, namely, the Massachusetts

NOTE: The writers are indebted to Drs. Louis I. Dublin and Alfred J. Lotka for encouragement and advice in the conduct of this study.

survey made by Bigelow and Lombard during 1929-1931.^{3,4} Inspection of Table 2 shows that, on the whole, the incidence of diabetes observed in the National Health Survey was somewhat greater than that in the Massachusetts survey.* The largest deviation between the two experiences is found among males of ages 70 to 79, and here it would seem that the Massachusetts figure is too low, a situation which may arise from the chance fluctuation of the small sample involved. Although the prevalence of diabetes may have increased from 1929-1931 to 1935-1936, the higher rates of the later period may also suggest better reporting in the National Health Survey than in the Massachusetts survey. In any event, the differences between the two experiences, on the whole, are not very great. They essentially confirm each other.

of this type, would be an understatement."

For the basic computations on the onset of diabetes according to sex and age, the data in Table 1 were used without adjustment. It is evident, therefore, that these data will provide minimum estimates of the situations considered. This is an important qualification of these estimates because in an appreciable number of cases diabetes exists in a form so mild that it may go undiagnosed or its diagnosis may be considerably delayed. As Joslin⁵ has pointed out, "Diabetics developing the disease after the age of 60 exhibit it generally in mild form; the exact time of onset of diabetes in older patients is not as easily ascertainable as in younger diabetics because the condition develops more insidiously."

Fortunately, trial computations of

Commenting on the quality of the data from the National Health Survey, Mr. Perrott² said, "I am inclined to believe that if the informant knew a person had diabetes, she would usually report that fact, even though the person were able to work. On the other hand, some such cases were naturally missed. Also, there would be cases unknown to the informant. . . . It seems evident that any estimate of the amount of diabetes present, based on information

these data show that any assumed percentage of understatement, even as high as 25 per cent, in the observed prevalence rates, provided it is invariant with sex and age, affects the onset rates emerging from our computations by practically the same percentage. It follows then that the rate of prevalence and annual onset and the chances of eventually becoming diabetic, as presented in the following pages, may be increased by any flat percentage considered appropriate to allow for any understatement in the observed data. No detailed consideration was given, however, to percentage allowances which

* For the purpose of this comparison, it was necessary to adjust the data of the National Health Survey by interpolation to the age grouping in which the data of the Massachusetts survey were presented.

* Onset rates were not computed at these ages in view of the small numbers involved in the basic data.

would vary with sex and age, because the results obtained from such allowances would not have a simple arithmetic relationship to those derived from the basic data.

Age and sex characteristics of diabetes prevalence rates: According to the National Health Survey, there were at least 3.67 diabetics per 1,000 persons in our urban communities in 1935-1936. Among males, 2.73 out of every 1,000 were diabetic, while among females the rate was appreciably greater, namely, 4.53 per 1,000. The rates for each sex rise steadily with increase in age, from low points, at ages under 15, of 0.35 per 1,000 males and 0.41 per 1,000 females to maxima in the age group 65 to 74 years, the rates here being 15.14 per 1,000 males and 23.80 per 1,000 females. At ages 85 and over, the rates for both sexes are somewhat over 6 per 1,000. The data supplied have been interpolated to provide diabetes prevalence rates for quinquennial age groups, as shown in Table 3, columns 2 and 3.

Along with the changes just described, there are correspondingly rapid

changes in the sex ratio of diabetes incidence with increase in age. Thus; under age 25, the rates for the two sexes are not much different; at ages 25 to 34 years, the females are higher by 20 per cent, at ages 35 to 44 by almost 60 per cent, and at ages from 45 to 64, their rates are almost double those for males. After age 65, the differential between the two sexes diminishes, the females being higher by almost 60 per cent at ages 65 to 74, by about 20 per cent at ages 75 to 84, and practically the same as that for males at ages 85 and over.

Age and sex distribution of diabetics: If it is assumed that the diabetes prevalence rates according to sex and age, as observed in the National Health Survey, prevailed in the general population of the United States during 1940, then there were at least 500,000 diabetics in the country during that year and their sex and age distribution was as shown in Table 4, columns 2 and 3. Males then constituted 38.5 per cent of the total cases and females 61.5 per cent. Over one-quarter of the total was under age 50, one-quarter was be-

* Based upon the rates shown in Table 3 and the United States census of population, April 1, 1940.

† Assumption based upon estimate of existing diabetics.

tween 50 and 60, and a little under half was at ages 60 and over. The peak, for quinquennial age groups, is found at ages 60 to 64 years, the males in this age group constituting 5.5 per cent of the total diabetic population and females 9.5 per cent. The average age of male diabetics was 55.6 years, and of the females, 56.7 years.

The foregoing estimate of a minimum of 500,000 diabetics in 1940 may be compared with several other estimates. In a review of diabetes incidence in the United States in 1930, Joslin, Dublin, and Marks³ estimated the number of diabetics as 400,000 at the most. For this estimate, they made use of the diabetes prevalence rates, specific for sex and age, as observed in the Massachusetts survey. More recently, the U. S. Public Health Service issued an estimate of 660,000 diabetics in the United States in 1937, basing its figure upon the findings of the National Health Survey, with an adjustment for under-enumeration.⁶ Their method involved multiplication of the crude overall diabetes prevalence rate observed in the Survey, by the total United States population

for 1937. To adjust for under-enumeration, the result was then "multiplied by the ratio of the 1935 death rate [from diabetes] in the United States (Bureau of the Census) to the Health Survey death rate." Both of these steps may introduce a bias toward too high an estimate. In the first place, the crude overall diabetes prevalence rate of the Survey is influenced in an upward direction by the fact that the Survey population contains an appreciable excess of females who, by themselves, have a higher prevalence rate than males. The crude prevalence rate based upon the National Health Survey, therefore, is hardly applicable without downward adjustment to the total population of the United States in 1937, in which males exceeded females in number. Second, the use of the ratio of the 1935 diabetes death rate in the whole country to that found in the Survey may lead to an over-correction. Since the deaths reported in the Survey were obtained by questionnaire, it is possible that deaths from diabetes were understated to a greater extent than cases. The cases reported were alive

on the day of the census, whereas the deaths may have occurred at any time within the preceding year, with a consequent increase in liability to error in reporting. The Public Health Service estimate for the number of diabetics in the country as a whole may be too high for another reason: namely, that the National Health Survey, of which they made use, represents the situation in an urban population, whereas indications are that the prevalence of diabetes, age for age, is lower in rural than in urban areas.^{3,7}

An estimate prepared by one of us (M. S.) for Joslin in 1939 yielded a figure of 1,000,000 diabetics for 1950. This was based upon an assumption of an average duration of 20 years from onset of diabetes to death; the assumption now appears to have been rather optimistic for the general population.⁸

GROWTH OF THE DIABETIC POPULATION

The outlook for the next few decades is that the number of diabetics will increase at a much greater rate than the population, and that the problem of diabetes will gain in importance. If it is assumed that the course of the diabetes prevalence rates according to sex and age as observed in the National Health Survey remain unchanged, then it is expected that the number of diabetics will increase by 18 per cent in the decade from 1940 to 1950, while the total population may grow only by 9 per cent. Present indications are that our total population will be at a maximum about 1985, when it will be 22 per cent greater than it was in 1940*; however, over the same time, the diabetic population may increase by 74 per cent. The more rapid increase of

the diabetic population than of the total population arises from two factors: first, the ever-increasing proportion of persons at the older ages; second, the more rapid increase in the number of females than of males at these ages.

In accepting the assumption that the course of the diabetes prevalence rates, according to sex and age, as observed in the National Health Survey, will continue to prevail without change, it is realized that no allowance is being made for the effect that organized efforts to make the general practitioner and the lay public more diabetes conscious may have upon future prevalence rates. It is quite likely that as these efforts become more successful, there will be an increase in diabetes case finding. Another factor that may raise the prevalence rates is the likelihood of further increases in the after-lifetime of diabetics beyond those already observed. It is obvious that by lengthening the life of diabetics, the proportion of them in our midst will increase. Still another consideration arises from the trend of our standard of living. As it continues to higher levels and is accompanied by a further increase in food consumption beyond the lessened physical requirements which result from our growing mechanization, the prevalence of diabetes may also show an upward trend. Although research is under way at present on the prevention of diabetes, the outlook for practical results appears too remote to warrant, at this time, the assumption of a favorable effect on future diabetes prevalence.

NEW DIABETICS

The data of the National Health Survey, together with information regarding mortality among diabetic patients of the George F. Baker Clinic during 1926 to 1929 reported by Joslin, Dublin, and Marks,⁹ provide the material with which it is possible, by a suitable actuarial technique, to esti-

* These estimates are based upon the "medium" forecast of population published by Thompson and Whelpton in *Estimates of the Future Population of the United States, 1940-2000*, National Resources Planning Board, Washington, D. C., 1943, Table 7, p. 45.

mate the age and sex distribution of persons becoming diabetic during the course of a year.* Although the mortality experience among the patients of the George F. Baker Clinic relates to a period somewhat earlier than the Survey, it is believed suitable for the present computations. The fact that the mortality experience of the Baker Clinic antedates somewhat the period of the National Health Survey is an actual advantage, as there would naturally be a lag between the results obtained in a large metropolitan medical center and the corresponding situation in the country as a whole, where treatment is sometimes inadequate or carried out under adverse conditions. Furthermore, the years 1926 to 1929 are at a sufficiently late date to insure that there was at that time already familiarity with the management of diabetes on insulin therapy, and the drug was in wide use.

Age and sex characteristics of diabetes onset rates: The first result emerging from the computations was a series of diabetes onset rates specific for sex and age—that is, a table of figures showing, for each sex and age, the chances that a non-diabetic will acquire the disease within one year. The results are shown for quinquennial age groups in Table 3, columns 4 and 5. As indicated earlier, the results represent the situation at a minimum. Correction for understatement in the Survey would give proportionally higher figures at each age.

An increase in diabetes onset with advance in age is apparent quite early in life; among young adults of ages 20 to 24 years, new cases arise annually at the rate of 2.8 per 100,000 for males and 3.8 per 100,000 for females. The onset rates mount with an accelerating rapidity up to about age 55—more so for women than for men. Thus, in the

age group 55 to 59 years, males acquire the disease at a rate of 102 per 100,000 or about 35 times the rate at ages 20 to 24, while females of ages 55 to 59 have a diabetes onset rate of 180 per 100,000, or about 45 times that of ages 20 to 24. After age 55, the diabetes onset rates increase at a less rapid pace and reach a peak rate of 125 per 100,000 males at ages 65 to 69 years, and a rate of 201 per 100,000 females of the same ages. The decrease in diabetes onset rates thereafter is quite rapid; for example, at ages 80 to 84, the annual onset rates for both males and females were about 66 per 100,000 persons. In this connection, attention is again called to the uncertainty of the time of onset of diabetes at the older ages.

The relative susceptibility of males and females to diabetes may be measured by the ratio of the onset rate for females to that for males of the same age. Thus, the ratio of the onset rates for females to males increases to a maximum of 2.2 at ages 40 to 44 years, and thereafter decreases, so that a ratio of 1.6 is found at ages 65 to 69 years, while after age 75 the rates of onset in the two sexes are not very different. The great acceleration in diabetes onset among females on approach of the menopause is indicative of the endocrine changes that are characteristic of that period of life.

Age and sex distribution of new diabetics: On the basis of the foregoing diabetes onset rates specific for sex and age, it is estimated that at least 50,000 persons in the United States became diabetics during 1940; about three-eighths were males and a little under five-eighths were females. The distribution of the new diabetics during 1940 according to sex and age is shown in Table 4, columns 4 and 5. Somewhat more than one-quarter of the new diabetics acquired the disease at ages under 50 years; almost one-half fell into the

* A brief outline of the method employed is given in a note at the end of this paper.

relatively narrow range from 50 to 64 years; and the remaining quarter were at ages 65 and over when they became diabetic. The average age of the new diabetics in 1940 was somewhat over 54 years for both sexes.

If we assume that the course of the diabetes onset rates according to sex and age as found in this paper remains unchanged in the future, then the new diabetics in 1950 will be 18 per cent greater than in 1940, and those in 1985 will be greater by 67 per cent. These increases are much greater than those of the total population. As in the case of the estimates of the total number of diabetics, the increases in the annual number of new cases arise from the growth of total population, from the increasing proportion of older persons, and from the increasing proportion of females in the population.

EVENTUAL DIABETICS IN THE POPULATION

Chances of eventually becoming diabetic: With the annual diabetes onset rates specific for sex and age computed in the manner described, and with an appropriate life table, it is a relatively simple matter to compute the chances that a man or a woman of any age will eventually become diabetic. The life table used for this purpose was based upon the mortality experience of white persons in the general population of the United States during 1935, this year being sufficiently close to the period of the National Health Survey. The results of the computation are shown in Table 3, columns 6 and 7.

Two characteristics become apparent from an examination of these data. In the first place, up to age 50, the chances of eventually becoming diabetic for females are almost twice those for males. Second, the chances rise very slowly from birth to a maximum at age 30, fall gradually until about age 50, and then fall quite rapidly at the higher

ages. Thus, among females, the chances of eventually becoming diabetic increase to a peak rate of 42.6 per 1,000 at age 30, then fall to 23.8 per 1,000 at ages 60 to 64, and to 10.0 per 1,000 at ages 70 to 74. In the case of males, the peak in the probability of eventually becoming diabetic is 22.8 per 1,000 at age 30, while in the age group 60 to 64 years, the figure is 14.8 per 1,000. In short, of our population under age 50, over 4 per cent of the females and more than 2 per cent of the males will become diabetic sometime during the course of their lives. These chances of eventually becoming diabetic are greater than the chances of eventual death from the disease since many diabetics die from other causes.

Age and sex distribution of the potentially diabetic population: An estimate of the age and sex distribution of eventual diabetics in the population at the census of 1940 is easily obtained. It simply calls for the multiplication of the numbers of the population (less those already diabetic), subdivided by sex and age, by the corresponding chances of eventually becoming diabetic. On this basis, it is found that at least 3,873,000 of those in the population of 1940 may eventually become diabetic; their age and sex distribution is shown in Table 4, columns 6 and 7. Of the total, 35.5 per cent are males and 64.5 per cent are females. About one-quarter of the number in the 1940 population who may eventually become diabetic will be found at ages under 15, and almost half are between the ages of 15 and 40.

SUMMARY

1. Using the diabetes prevalence rates according to sex and age as observed in the National Health Survey, it is estimated that there were at least 500,000 diabetics in the United States in 1940. Almost two-fifths of the diabetics were males and over three-fifths were

females. One-half of the total diabetics were at ages 60 and over.

2. During the next few decades, the number of diabetics in the United States will increase at a much greater rate than the total population. From 1940 to 1950, an increase of 18 per cent may be expected in the number of diabetics, while the total population is expected to grow only by 9 per cent.

3. At least 50,000 persons in the United States became diabetic during 1940; about two-fifths were males and three-fifths females. Not quite half were under 55 at the onset of their diabetes; somewhat more than one-quarter became diabetic between ages 55 and 64; and one-quarter were at ages 65 and over when they developed the disease.

4. Of our population under age 50, over 4 per cent of the females and more than 2 per cent of the males will eventually become diabetic.

NOTE ON METHOD

This note outlines the procedure followed in arriving at the diabetes onset rates.

In a stationary (life table) population let

l_x = number who live to attain age x

r_x = proportion of persons at age x with diabetes

$l_x^a = r_x \cdot l_x$ = number of diabetics attaining age x

i_x = number becoming diabetic during the year of age x to $x + 1$

q_x^a = chance, per head, that a diabetic just attaining age x will die from any cause within the year of age

d_x^a = number of deaths from any cause at age x to $x + 1$ among diabetics in the stationary population

Then

$$(1) l_x^a + i_x - d_x^a = l_{x+1}^a$$

Assuming that the new diabetics at age x to $x + 1$ were exposed to the risk of death as diabetics at that age for one half year on the average, and further, that their mortality was not different from that of those already diabetic, we have

$$(2) d_x^a = q_x^a (l_x^a + \frac{1}{2} i_x)$$

Substituting (2) in (1) and solving

$$i_x = \frac{l_{x+1}^a - l_x^a (1 - q_x^a)}{1 - \frac{1}{2} q_x^a}$$

The chance that a non-diabetic of age x will become diabetic within the course of the year of age is

$$p_x^a = \frac{i_x}{l_x - l_x^a}$$

The chance of eventually becoming diabetic at or after age x is

$$\frac{\sum_{t=0}^{t=\infty} i_{x+t}}{l_x - l_x^a}$$

The life tables used were those for white males and white females in the general population of the United States in 1935.

Outbreak of Typhoid Fever with Orange Juice as the Vehicle, Illustrating the Value of Immunization

T. G. DUNCAN, M.D., J. A. DOULL, M.D., DR.P.H., F.A.P.H.A.,
E. R. MILLER, AND HULDAH BANCROFT, PH.D.

of Health, Cleveland, Ohio; and Assistant Professor of Biometrics,
School of Medicine, Western Reserve University, Cleveland, Ohio*

A SMALL localized epidemic of typhoid fever occurred in the E home, a residential hotel for business women, in Cleveland, Ohio, during January, 1944. Approximately 360 young women including 150 SPARS lived in the Home, among whom 18 cases of typhoid fever developed with 1 death. The outbreak is interesting because of the unusual vehicle of the infection and because it affords an opportunity to observe the influence of vaccination against *Eberthella typhosa*.

The first hint of the epidemic came on January 16, 1944, when a private physician notified the Division of Health that he was treating two young women suffering from fever of unknown origin. The first of these had been hospitalized on January 5, the second on January 14. Both were residents of the E Home. On January 16, a third resident was hospitalized with similar symptoms. On January 17, blood serum from the first patient agglutinated *E. typhosa* in a relatively high titer (*H* 1:640, *O* 1:2560).

Epidemiological investigation was begun on January 18. Stool cultures and blood specimens were obtained immediately from all individuals who had had any contact with food handling

since November 1, 1943, including those who had left the service of the hotel. A plumbing survey was instituted and water samples from outlets on every floor were examined. Serving of food within the hotel was discontinued on January 19. All guests and employees were checked daily for suspicious symptoms.

Letters were sent to all former guests who had resided at the Home during December and January with the request that the Division of Health be notified of any illness occurring within 30 days of departure from the Home. Replies were received from 23 of 49 letters sent. Information obtained revealed that 3 cases had occurred in this group, 1 of which had terminated fatally.

The dates of onset of the 18 reported cases were as follows:

Onset	Cases	Onset	Cases
December 31, 1943	1	January 13, 1944	1
January 5, 1944	1	15, " "	1
6, " "	1	17, " "	1
8, " "	2	18, " "	1
9, " "	1	19, " "	1
10, " "	1	20, " "	2
11, " "	2	28, " "	1
12, " "	1		
		Total	18

In 12 of the 18 cases, blood cultures and Widal's were positive. In 5 others, Widal's and stool cultures were positive. For one out-of-town case, blood, stool, and urine cultures were negative, but the Widal reaction was positive (*H* 1:40, *O* 1:160).

The attack rates for the civilian group and the SPARS are given by age in Table 1.

December 25 to January 16, when she quit her job, she prepared only part of the orange juice. She began preparation of the juice when she first arrived in the morning. The juice was allowed to stand at room temperature until served. Careful questioning, both of the woman herself and of other employees, could elicit no evidence of other contact on her part with any food

TABLE 1
Age-specific Attack Rates from Typhoid Fever for Civilians and SPARS

Age in Years	Civilians			SPARS			Total		
	Number Exposed	Number Attacked	Per cent Attacked	Number Exposed	Number Attacked	Per cent Attacked	Number Exposed	Number Attacked	Per cent Attacked
18-19	22	1	4.5	0	0	22	1	4.5
20-29	131	14	10.7	136	1	0.07	267	15	5.6
30-39	24	2	8.3	13	0	0.00	37	2	5.4
40+	2	0	0.0	0	0	2	0	0.0
Unknown	15	0	0.0	32	0	0.00	47	0	0.0
Total	194	17	8.8	181	1	0.06	375	18	4.8

Results of all water analyses were negative. Three consecutive stool cultures taken not less than 24 hours apart and Widal tests were negative for all but one of the 25 persons handling food. This person was a colored female with a negative history of typhoid fever. Her first stool specimen taken on January 23 was positive for *E. typhosa*. On January 24 the Widal for this individual showed for the *H* antigen plus-minus in dilution of 1:80 and for the *O* antigen positive in dilution of 1:160. Following a second positive stool culture for this individual, she was hospitalized for further study. Positive stool cultures were obtained in the hospital on February 1, 2, 4, and 25.

This woman was first employed by the Home on September 13, 1943, as a dishwasher working only from 6 to 9 A.M. Until December 15 she did nothing but wash dishes. On that day she was given the task of preparing the orange juice for breakfast. She alone prepared orange juice from that date until December 25, at which time she was given assistance, so that from

served, nor was any evidence obtained which would incriminate other articles of food.

SPARS and civilians breakfasted together in the cafeteria. All of the 15 local cases customarily ate breakfast at the hotel.

Fourteen stated that they drank orange juice regularly for breakfast. One girl did not remember whether she had had any during the preceding month. However, the proportion of the non-cases eating breakfast at the hotel who drank orange juice was also high. Out of 220 questioned 199 gave such history. Notwithstanding this fact, it was concluded that orange juice must have been the vehicle.

The distribution of the dates of onset did not suggest a mass infection at one time. There was a proved carrier responsible for only one article of food, orange juice. All but one of the local cases were known to have consumed orange juice. As supporting evidence, orange juice was inoculated with typhoid bacilli isolated from the carrier and incubated at room tempera-

ture. Viable bacilli were recovered up to 6 days after inoculation.

Vaccination records were available for only 143 of the 181 SPARS who were known to have resided at the Home during December and January. The balance had been transferred to other posts and no attempt was made to obtain their records. It may be assumed, however, that all had been vaccinated. Of the 143, all had been immunized against *E. typhosa* since February, 1943, but 12 had received their last dose during October or November. The only case occurring among the SPARS was in an individual in this group who had received her last dose on November 30, 1943. The onset date for this case was given as January 20, less than 2 months later.

Information regarding vaccination was obtained from 194 civilians living in the Home. Seven of these individuals had had a previous attack of typhoid fever. Of 27 who claimed to have had 3 doses of typhoid vaccine 13 had been vaccinated prior to 1941 and 14 subsequently. One claimed to have only one dose and 2 did not know how

many doses had been given. No cases occurred among those with history of a previous attack or with history of any vaccination. Seventeen cases occurred among the 140 remaining members of the group.

Combining the two groups and omitting the 7 who had had previous attacks, there were 368 individuals for whom immunization histories were known. If all persons giving history of immunization, regardless of the number of doses or date on which it was given, be considered as immunized, there were 211 immunized persons. Among these only 1 case occurred. Among the 140 who were not immunized there were 17 cases, giving an attack rate of 12.1 per cent. If the immunized had suffered this rate of incidence there would have been about 25 cases in the group. That such a difference could have occurred by chance is of course highly improbable. So far as could be ascertained the exposure of the two groups was on the average equal, accepting orange juice as the vehicle. It is concluded therefore, that the difference must be attributed to active immunization.

Placement Unit for Nurses

The United States Employment Service has opened a counseling and placement office at 119 West 57th Street, New York, N. Y., for Army and Navy nurses and other veterans of the medical services of the armed forces. An advisory committee representing the fields of medicine, nursing, and public health is serving in a consultant's capacity to the new venture. Service is on a 24 hour basis and without charge to the registrant.

Approximately 50,000 persons from the New York City area have served in medical and health assignments in military service. Many will wish to find new positions on their return to civilian life, or to prepare themselves by additional education for a specialty. The U.S.E.S. is organized to give advice and information regarding special training under the G.I. Bill of Rights as well as to fill the needs of employers seeking qualified personnel.

Epidemiological Studies on Infectious Hepatitis*

WALTER P. HAVENS, JR., MAJOR, MC, AUS

*Section of Preventive Medicine, Yale University School of Medicine,
New Haven, Conn.*

IT is largely due to the military importance¹⁻¹⁷ of infectious hepatitis that renewed interest has been stimulated in this disease. Numerous reports have recently described its prevalence, particularly in the Mediterranean area where it has occurred among American,^{14, 16, 17} British,^{6, 8, 11-13} Italian,⁷ French,¹ and German²⁻⁴ troops as well as the civilian population of Palestine.¹⁸⁻²⁰ Although the relationship is not known, there is no reason to believe that this type of infectious hepatitis differs from that seen in outbreaks of epidemic jaundice which have been noted in the United States,²¹⁻²³ or differs from the disease which has been frequently described as infective hepatitis in England,²⁴⁻²⁶ or as *hepatitis epidemica* in Scandinavia,²⁷ Germany,^{28, 29} and many other parts of the world. There is also no ready means of differentiating it from catarrhal jaundice^{9, 10} except that the latter term has been reserved more for sporadic than epidemic cases. Furthermore, it is not clear whether post-vaccinal hepatitis,³⁰⁻³⁶ transfusion jaundice,^{37, 38} and homologous serum jaundice³⁹⁻⁴⁹ may not all be examples of the artificial production of the same disease. The lack of susceptible laboratory animals and specific immunologic tests has

made more difficult the solution of these obscurities. These and other questions are unsettled and deserve further study but on a few points at least there is agreement, namely, infectious hepatitis can be differentiated from spirochetal jaundice (Weil's disease) and from yellow fever; it also can be differentiated from the jaundice of infectious mononucleosis, of malaria, and certain other infections.

It is strange that a disease which is so common and has become so important from a military standpoint should have been so poorly defined until recently. Only a limited number of authors such as Blumer²¹ and a few others^{22, 23, 50} have called attention to the public health aspects of infectious hepatitis in this country.

It is the object of this paper to review these aspects in the light of new information and to mention experiments with human volunteers which are related to the epidemiology of the disease.

EPIDEMIOLOGY

Geographic Distribution: Reports of 19th century outbreaks cover a wide area and it is probable that infectious hepatitis occurs throughout the entire world, but in the absence of specific diagnostic tests its exact distribution is unknown. In 1923 Blumer²¹ assembled information on many epidemics which had occurred in almost every section of the United States. Outbreaks have also

* Representing work done for the Neurotropic Virus Disease Commission of the Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, in the Preventive Medicine Service of the Office of The Surgeon General, U. S. Army, Washington, D. C.

been reported from Iceland,⁵¹ England,²⁴⁻²⁶ Europe,^{3, 53} Scandinavia,⁵² Poland and Rumania,² India,⁵⁴ and Africa.⁵⁵ The eastern half of the Mediterranean area^{6, 16, 17, 60} represents a region where this disease has been particularly prevalent among troops both in World Wars I and II with cases numbering in the tens of thousands in the years 1941-1944. Native populations either civilian or military, in the "epidemic areas" are usually less susceptible than are troops or immigrants from abroad. Little is known of the general climatic or exact environmental conditions which influence its spread, but at least these are not sharply limited to any particular latitude. It is universally agreed, however, that this disease flourishes best under poor sanitary conditions.

Season: In certain parts of the world there is a distinct and rather sharp seasonal trend with an increase in prevalence coming on in the fall of the year and often building up to epidemic proportions during late fall and early winter. The epidemic season is by no means limited to fall and early winter, however, for as has been the case in this country, it may begin in the fall and extend through the whole winter and well into the spring. The explanation of this seasonal trend is unknown.

Age: In the United States and many other areas, infectious hepatitis is commonly seen in the civilian population as a disease of childhood. The age group in which most of the epidemic cases fall ranges from 5 to 17 years. It is common enough too, however, among young adults, to which military epidemics, as well as outbreaks among university students testify. Inasmuch as the childhood form of this disease is very mild and easily overlooked, it has been suggested that infectious hepatitis is far more common than is usually realized, and that most

adults have been exposed in early life and have even had the disease in unrecognized form, so that they have acquired a certain degree of immunity.

Epidemics: In civilian populations, outbreaks which involve several hundred people (usually children) over a period of one or two months are common. Institutional and family outbreaks are traditional. Favored sites are institutions, camps for children, and military camps. In orphan asylums, as many as one-quarter or one-third of the population may be infected. In families the usual sequence of events is, that one member first acquires the disease and then 3 or 4 weeks later it appears in one or more other members. Within military units the case rate can occasionally reach such proportions as 40 or 50 per cent of the total command. Such severe epidemics have, as mentioned before, occurred under poor sanitary conditions, often when and where dysentery is or has been rife.

Predisposing factors which may affect host resistance to this particular infection are probably important, particularly under military circumstances, although their existence rests on circumstantial evidence alone. They are: poor diet, alcohol, poor living conditions, exposure during active campaigns.

A high prevalence of hepatitis in syphilitic patients undergoing intravenous therapy has been noted on more than one occasion. It is not clear whether this is due to an increased vulnerability of the liver for invasion by the virus, or to the possible artificial transmission of serum jaundice.⁵⁶

Incubation Period: In most epidemics this period has been estimated to be between 20 and 40 days, averaging 26-28 days. In experimental human cases, induced by feeding serum or feces, the average incubation period has been 25 days. It may occasionally be as short as 16 days or prolonged to 85 days.

Natural Transmission: For information on this point one would be concerned about the circumstances under which epidemics occur and it is well to recall that water-borne epidemics have been reported.^{52, 57} Recently Neeffe and Stokes⁵⁸ have reported the transmission of hepatitis without jaundice to human volunteers by the oral administration of water from a well of a children's camp where a large outbreak of infectious hepatitis had occurred. This may represent one manner in which infectious hepatitis normally spreads although it is probable that other ways also exist. There is good evidence to suspect the intestinal-oral circuit as one of the natural routes of spread. This theory is based in part on field observations and in part on the investigative work quoted below, which indicates that the virus is in the feces during the acute phase of the disease, and that infectious hepatitis can be transmitted to human volunteers by feeding infected feces. It fits in with facts observed in military populations, with its high prevalence in areas where camp sanitation is bad, and its frequent association with intestinal diseases. Kirk's⁵⁹ study of infectious hepatitis, among New Zealand soldiers at El Alamein in Egypt in 1942, led him to believe that the disease was spread by flies carrying the infection from human excreta. It has further been suspected that the prevalence of bacillary dysentery or Salmonella infections may either predispose in some unknown way to the acquisition of hepatitis or that these organisms are prone to act as secondary invaders.^{60, 61}

The question of possible transmission by biting insects also deserves consideration, for a disease which is obviously infectious, and in which the virus is in the blood, should be regarded potentially as a disease which might be spread by blood sucking insects, until proved otherwise.

In this connection its artificial spread through the use of improperly sterilized syringes is a point of consideration described by Droller.⁶² The extreme viability of the icterogenic agent, the infectiousness of small (0.01 ml.) quantities of serum, all point to the fact that it has probably been transmitted artificially more often than is realized. These impressions should all be reviewed critically in the light of newer experimental work on this disease.

Etiologic Agent: As yet this so-called icterogenic agent has not been actually "isolated" in the sense that it has been seen, cultured, or transmitted experimentally to laboratory animals. This agent or "virus" is present in the blood and feces of patients in the pre-icteric and early icteric phases of the disease; it may also be present in the urine at this time. It withstands heating to 56° C. for at least ½ hour.⁷⁰ It has also been filtered through bacteria tight filters and for this reason, has been classified as a virus.^{67, 69, 70} Data on the limits of time (during the incubation and during the active disease) in which this "virus" may be found in the human peripheral blood are scanty, but there is good reason to believe that the pre-icteric and early icteric stage is the period in which the virus is most readily demonstrable in the blood and feces. The limits of the intestinal carrier state remain to be accurately determined.

Attempts to infect common laboratory animals,^{6, 71} including many rodents, many species of monkeys, and even chimpanzees,⁷² have failed. It is possible that the "jaundice" transmitted to pigs in Denmark by Andersen⁷³ was infectious jaundice of this type. More recently German workers claim not only to have propagated this agent in the developing chick embryo,^{74, 75} but to have infected birds^{76, 77} with it. These reports have not however, been confirmed.⁷⁸ To

date therefore, almost all of the properties of this virus have been determined by using man as the experimental animal. Such experiments on human volunteers have also yielded some information as to the routes with which man can be readily infected.

TRANSMISSION EXPERIMENTS WITH HUMAN VOLUNTEERS

In the search for the natural mode of transmission of infectious hepatitis various experiments have been reported of infection following feeding icterogenic material to human volunteers. In Table 1 are recorded all of the positive results with jaundice reported so far, of attempts to infect human volunteers with infectious hepatitis by both the oral and parenteral routes.

The early work of Voegt⁶³ probably showed that in patients with infectious hepatitis the duodenal contents taken on the 24th and 30th days of disease and possibly urine and hemolyzed

erythrocytes, are infectious when fed to human volunteers.

More recently MacCallum and Bradley⁶⁴ have demonstrated that the stools of patients in the pre-icteric state or in the first days of jaundice of infectious hepatitis contain an icterogenic agent which can be transmitted to human volunteers by feeding, producing infectious hepatitis after an incubation period of 27-31 days.

These latter results have been confirmed and somewhat enhanced by experiments conducted by the Neurotropic Virus Disease Commission of the U. S. Army.

The strain of infectious hepatitis virus used in this laboratory was originally obtained from the stool of a patient (BE) who contracted epidemic infectious hepatitis in Sicily.⁶⁵ This agent has been through three passages in human volunteers and is regularly present in the feces and serum of patients in the pre-icteric or early icteric

phase. Eleven human volunteers have been fed either feces or serum containing this strain of icterogenic agent, and of these, 8 have contracted infectious hepatitis with incubation periods ranging from 16 to 34 days. The ease of experimental transmission by feeding and the presence of virus in the feces indicate that the intestinal-oral route may be of importance in the natural spread of the disease.

It is of interest that when inoculated parenterally (in serum) the work of others has shown that different strains of "virus" produced infectious hepatitis with varying incubation periods. In this laboratory 17 volunteers have been inoculated subcutaneously and intracutaneously, and of these, 9 contracted the disease after 20-31 days. These results are in agreement with some and in contrast with those of certain other workers, employing different strains; the latter frequently have found much longer incubation periods following parenteral inoculation of human volunteers with infectious serum (see Table 1).

Such divergent results in the reports of various groups of investigators suggest that different strains of virus may exist. This is supported in part by recent work in this laboratory with one strain in which an effort was made to determine if size of dose or route of inoculation had any effect on the length of incubation period of infectious hepatitis caused by our strain of virus. In one experiment equal amounts of the same icterogenic agent were fed and inoculated parenterally into human volunteers.⁷⁰ In another experiment the same icterogenic agent was inoculated in graded amounts of the order of 1-, 10-, and 50-fold increasing doses (0.01 ml. to 0.5 ml. of infectious serum).⁷⁹

The results revealed no appreciable difference in the incubation period dependent on route of inocula-

tion or size of dose, in the range of dosage used.

IMMUNITY IN INFECTIOUS HEPATITIS

The natural history of the disease supports the concept of a widespread immunity in the general population, incited by clinical or subclinical infection. Suggestive evidence along this line has been offered recently by Stokes and Neefe⁸⁰ and others^{81, 82} in their demonstration of the protective effect of human gamma globulin against infectious hepatitis when administered during the incubation period. Preliminary experiments⁸³ with human volunteers indicate that an attack of infectious hepatitis provides immunity against reinfection with a similar strain of virus.

The question of whether the immunity resulting from a single attack is effective against multiple strains of the virus deserves much more study. It has already been pointed out, for instance, that the immunologic relationship between the naturally occurring disease, infectious hepatitis, and homologous serum jaundice is poorly defined. The etiologic agent, or agents, of the two conditions have certain properties in common: both are filtrable and withstand heating to 56° C. for at least 30 minutes. Both conditions may be transmitted by parenteral inoculation. Infectious hepatitis can be transmitted to man by the oral route and the etiologic agent is in the stools. In contrast to this the agent of homologous serum jaundice has not been demonstrated in the stool,^{68, 84} and successful transmission experiments by the oral route are limited.⁸⁵

But, as mentioned, the question of cross-immunity between these two conditions requires clarification. Men who have had serum jaundice do acquire infectious hepatitis. Experimentally, the evidence for cross-immunity is contradictory. Oliphant⁶⁶ has demonstrated

protection against a strain of infectious hepatitis in patients convalescent 9-18 months from homologous serum jaundice while the results in our laboratory⁸⁶ have failed to show such protection; for when patients convalescent 6 months from homologous serum jaundice were reinoculated with a strain of infectious hepatitis they contracted the latter disease.

SUMMARY

The epidemiological features of infectious hepatitis and the experiments on the transmission of this disease to human volunteers have been reviewed.

Evidence has been cited that the etiologic agent is filtrable and is in the stool, serum, and possibly urine of patients in the acute phase of the disease. It may probably be classified as a virus. Other properties including its resistance to heat and transmissibility to human volunteers by feeding or parenteral inoculation have been discussed.

The fact that this agent is in the stool and may be transmitted by feeding to human volunteers suggests that the intestinal-oral route may be important in the natural spread of the disease.

The Nobel Prize Awards

Sir Alexander Fleming, of London, and Sir Howard W. Florey and Dr. Ernst B. Chain, of Oxford University, recently were awarded the 1945 Nobel Prize for physiology and medicine. The 1943 award was made to Drs. Edward A. Doisy, Professor of Biochemistry at the St. Louis University School of Medicine, and Henrik Dam of Copenhagen, who was in the United States at the time. The 1944 award was presented to Drs. Joseph Erlanger, Professor of Physiology at Washington University School of Medicine, St. Louis, and Herbert Spencer Gasser, Director of the Rockefeller Institute, New York. According to the Stockholm announcement, the 1945 award is made

in recognition of the pioneer work of these three investigators in the discovery of penicillin and its healing effects in treating infections. The recipients will share equally in the prize, which amounts to about \$30,000. Fleming's discovery of penicillin as an antibiotic agent was published in 1929; Florey and Chain demonstrated a method of obtaining penicillin in relatively pure form and first employed this substance clinically during the years 1938 to 1940. Fleming, Florey, and Chain are universally recognized as the pioneers in penicillin research, although other workers have contributed greatly to the preparation of penicillin and its clinical use today.

Proposed Report on the Educational Qualifications of Nutritionists in Health Agencies^{*†}

I. GENERAL SCOPE OF THE FIELD

In view of the great advance in the science of nutrition and the realization on the part of public health workers that proper nutrition of individuals plays an important part in maintaining well-being, there is an increasing demand for properly trained workers to carry on nutrition programs in the field of public health.

The past few years have seen a marked increase in the employment of nutritionists by public health agencies, both official and voluntary. The same period has marked the beginning of research in nutritional status and food consumption as a function of public health agencies and also of nutrition service as an aspect of industrial hygiene.

Many official public health agencies are charged with responsibility for institutional care of fairly large numbers of people, notably in tuberculosis sanatoria and in hospitals and wards for the care of crippled children. In these institutions, the dietary department requires competent supervision both because diet is such an important aspect of treatment and also because food is likely to be one of the major items in the budget.

It is estimated that there are at least 400 public health nutritionists at work at the present time. Official public health agencies (state, county, and city) undoubtedly lead in the employment of nutritionists, with the American National Red Cross and its local chapters in second place. Among other health agencies maintaining nutrition service are: visiting nurse associations, community health councils, and tuberculosis associations. Although the war has given impetus to the public health nutrition movement, very few agencies would seem to have built up such large staffs as to point to marked retrenchment with the return to peacetime health programs.

Because of the developments listed above, public health agencies are seeking not only more nutritionists but nutritionists capable of performing specialized functions and of supervising the services of staff workers in positions of lesser responsibility. The original report on Educational Qualifications of Nutritionists in Health Agencies (approved by the Governing Council of the American Public Health Association, October 13, 1941) covered only the type of position most common at that time, namely that of a consultant who works under the administrative direc-

* The Committee on Professional Education of the American Public Health Association publishes this report before transmittal to the Governing Council in order to permit the members and Fellows of the Association to review it and to offer criticisms and suggestions in the further consideration of the report. Suggestions should be mailed promptly to the Committee on Professional Education, A.P.H.A., 1790 Broadway, New York 19, N. Y.

† This report, like all other statements of the committee on professional and technical qualifications in

public health, is subject to periodic revision in order that it may be kept abreast of the best thought.

† This proposed report is a revision of the Report on the Educational Qualifications of Nutritionists in Health Agencies approved by the Governing Council on October 13, 1941, and is intended to supersede the earlier report. It has been approved for publication in the respective Journals of the American Dietetic Association and the American Home Economics Association by their Executive Boards, with minor editorial changes.

tion of a major division of the health agency and who is largely responsible for the technical content of her program.

The report has been widely used by (1) colleges and universities training nutritionists and those arranging public health nutrition curricula; (2) administrators of civil service and merit systems; (3) employers selecting nutritionists, and (4) individuals preparing themselves for service in this field or arranging additional preparation for themselves or their staff.

Although the recommendations have proved helpful, their limitations have become increasingly evident. The subcommittee is agreed that the time has come to act on the implied promise in the footnote to the original report: "This report like all other statements of the Association on professional and technical qualifications in public health, is subject to periodic revision in order that it may be kept abreast of the best thought." The recommendations that follow cover the principal types of nutrition positions in the field of public health at the present time. It is impracticable to insist that all present incumbents comply with these requirements; they are recommended for application to candidates applying for appointment.

II. STATEMENT OF FUNCTIONS

A. The nutritionist in a public health agency is a qualified professionally trained person who directs or carries on a program of activities dealing with the application of the scientific knowledge of nutrition to the promotion of positive health, the prevention of ill health, and the dietary control of disease. The nutrition program of a health agency is directed toward strengthening the service that the agency is rendering in determining the health status of the population served, in dealing with the causes of ill health, in caring for

the sick entrusted to its care, and in promoting well-being among groups and individuals through better food practices.

The function of a highly organized nutrition service of a large health agency will include most, if not all, of the following activities. In smaller health agencies the range of functions will be narrower.

1. Organizing and carrying out a program to:

a. Control dietary deficiency diseases through determining their prevalence and distribution and, if they are found to constitute a public health problem of some magnitude, by conducting or participating in clinics for their diagnosis and treatment.

b. Prevent dietary deficiencies and promote health through encouraging wise production or selection and proper processing, preparation, and use of the foods necessary for optimum nutrition. Such programs frequently call for coöperation between the health agency and agencies and organizations in the fields of agriculture, education, welfare, industry, medicine, nursing, and dentistry.

2. Studies and surveys:

a. On prevailing food practices of the population of a given area or of special groups, such as school, children, industrial workers.

b. On cost, availability, and use of foods needed to furnish an adequate dietary, these to be used as guides for setting up nutrition programs.

c. On the nutritional status with respect to certain factors of the population of a given area or special groups, such as residents of a home for the aged.

d. On the effect on nutritional status of modifications in the diet.

e. On the effectiveness of nutrition programs in improving food supplies and practices.

3. Preparation and assembling of materials for nutrition education and reviewing the nutrition content of all educational materials prepared or distributed by the agency.

4. Professional education. Participation in the field training of public

health students and in the orientation and in-service training of the staff of the health agency.

a. Imparting to public health workers and allied personnel a working knowledge of human food needs, nutritive values of foods, and methods of improving nutritional status in cooperation with whatever specialized personnel in nutrition may be available in the area served.

b. Participation in the pre-service and in-service training of nutritionists and of workers in related fields, such as educators, social workers, managers of food service in schools, child care centers, or institutions.

5. Consultation services for workers in health or allied agencies in regard to nutritional needs and dietary practices of individuals, families, institutional and industrial groups, or a cross-section of the population of a given area, with the object of planning ways of meeting these needs and improving practices within the resources—actual or potential—of the individuals or groups under consideration.

6. Individual and group instruction of adults and children on food, nutrition, and budgeting, in connection with health conferences or clinics or with the educational or service program of the health agency in schools or the agency's program of community education.

7. Compilation and, if necessary, preparation of nutritionally adequate food market orders, menu plans, and recipes, adjusted to various cost levels, to racial, religious, or regional food practices, and to individuals in unusual circumstances, such as night shift workers or persons living outside of family groups. Similar service for therapeutic and other special diets recommended by physicians.

8. Cooperation with welfare agencies in formulating budget standards for food to meet the nutritive needs of individuals, family groups, and institutions, and in calculating the cost of

standard food budgets at prevailing prices.

9. Inter-agency relationships. Bringing about closer relationships between the health agency and other agencies carrying on educational, service, or research programs in nutrition.

10. Coordination of nutrition programs. Participation in the organization and continuing activity of coordinating councils in the field of nutrition and health and in the organization of communities for unified effort toward the improvement of nutritional status and the maintenance of a satisfactory level of nutrition once attained.

B. *Classification of different grades*

The nutrition positions in health agencies may be grouped into 3 grades: (1) The director of a nutrition service in a health agency with responsibility for a staff of workers; (2) the nutritionist who acts primarily as a consultant and neither has responsibility for a staff of workers nor receives close technical supervision; and (3) the staff nutritionist working under close technical supervision from the director of a nutrition service. These grades are described in somewhat more detail in connection with the statements of education and experience under III and IV.

III AND IV. BROAD EDUCATIONAL BACKGROUND (UNDERGRADUATE) AND GRADUATE EDUCATION

A. *For a director of a nutrition service in a health agency with responsibility for a staff of workers.* The essential qualifications for the incumbent of this position are broad grasp of the science of human nutrition, knowledge of public health administration, and administrative ability. The director cannot be expert in every aspect of public health nutrition but should be able to recruit and supervise a staff that together will possess competence in all the major

fields. Directors of nutrition services in health agencies may have acquired the necessary qualifications through any one of several backgrounds of education and experience but these backgrounds will have certain elements in common, as indicated in the following paragraphs:

1. Education. Human nutrition should be the subject of major interest. A director of nutrition service should have at least one year of full-time graduate academic credit in addition to the undergraduate academic training leading to a baccalaureate degree or its equivalent in pre-medical training. The combination should be so chosen as to qualify the student for participation as a nutritionist in the public health field.

Colleges and universities offer graduate training in public health nutrition in professional schools of public health or in postgraduate programs in nutrition based on undergraduate preparation in home economics. The content and extent of graduate study required to supply this training will vary according to the type of undergraduate preparation, the interval since such work was completed, the relevancy of any work experience, and the scope of the program directed.

a. The *undergraduate course of study* leading most immediately to preparation for public health nutrition is that qualifying the student for a baccalaureate degree with a major in foods and nutrition as offered in a course in home economics. Such a curriculum includes as a requirement basic courses in chemistry (including physiological or biochemistry), physiology, bacteriology, the social sciences (economics, sociology, and psychology), human nutrition, food study (selection, marketing, preparation), and educational methods. Electives often include introductory courses in statistics, child development, journalism, and public speaking.

b. Students whose undergraduate major has been in the biological sciences, social sciences, education, or pre-medical studies, will need to supplement such preparation with the required courses listed above.

c. The minimum of one year of *full-time graduate academic study* should feature advanced courses in human nutrition, and together with the undergraduate study should give a working knowledge of: methods and techniques of nutrition investigations and dietary studies, child hygiene and development, public health administration, health education, principles of supervision, community organization and resources, and social case work.

d. A course in hospital dietetics accredited by the American Dietetic Association is a desirable addition to other types of graduate preparation but is substitutable only in so far as it carries academic credit in courses essential for public health nutrition. Completion of the requirements for a degree as doctor of medicine or doctor of philosophy in biochemistry constitutes adequate educational preparation for the field of public health nutrition when the students have had full courses for academic credit in human nutrition and its applications in the field of public health.

e. Field work in a health agency carrying on a nutrition program under the supervision of a qualified nutritionist should be provided preferably at the graduate level.

2. Experience *

a. Minimum of 4 years of successful, paid experience as a nutritionist in a health agency or a welfare agency carrying on a nutrition and health program. At least one year must have involved responsibility as a supervisor of both professional and clerical staff or as a consultant, or

b. Two years in the above plus 4 years in any one of the following positions or any combination of them:

(1) Therapeutic or teaching hospital dietitian

(2) Physician engaged in clinical medicine, teaching of medical students, research, or public health

(3) Dietitian or nutritionist employed by a food clinic, child development center, school system, nutrition council or committee

(4) Research worker in human nutrition

(5) Teacher of foods and nutrition in a school, college, or university, or adult education program

* Candidate should have had part of training and experience indicated within 4 years of the time of application.

(6) Agent or food and nutrition specialist in the agricultural extension service or farm security program

3. Substitution of education for experience.

Each year of relevant graduate study beyond the minimum of 1 year may be substituted for 1 year of experience except that 2 years of the type of experience described under 2a is not substitutable.

4. Personal qualities:

- a. Executive, organizing, and administrative ability
- b. Physical fitness
- c. Ability to gain confidence of administrators and staff and to win and retain cooperation of coworkers and public
- d. Skill in analysis of situations and in presentation of material

B. For a nutritionist who acts primarily in a consultant capacity and neither has responsibility for supervision of a staff of workers nor receives close technical supervision. The services rendered may be along either of two lines: (1) general consultation to a given area, or (2) service limited to a special field such as consultation in group or institutional feeding, or conducting a program of discovering and controlling nutritional deficiency diseases.

1. Education *

- a. As outlined in A 1 of this section, undergraduate college work and satisfactory completion of the equivalent of at least 1 year of full-time graduate academic credit, chosen in relation to the previously mentioned basic training so as to qualify the student for participation in the public health field. For service in a special field, the graduate work should provide special training. For example, the consultant in group feeding should have majored in institution administration and completed apprentice training approved by the American Dietetic Association in hospital dietetics, institutional management, or industrial feeding, whereas a nutritionist in charge of a program of diagnosis and control of deficiency disease should have had complete medical training.

b. Field work in a health agency carrying on a nutrition program under the supervision of a qualified nutritionist should be provided preferably at the graduate level.

2. Experience *

- a. Minimum of 2 years of successful, paid experience as a nutritionist in a health agency or a welfare agency carrying on a nutrition and health program, or
- b. One year in the above plus 2 years in any one of the positions listed under A2b or any combination of them.

3. Substitution of education for experience:

Each year of relevant graduate study beyond the minimum of 1 year may be substituted for 1 year of experience up to a maximum of 1 year for a general consultant or 2 years for a nutritionist assigned to a research project, or a program requiring medical training.

4. Personal qualities:

- a. Physical fitness
- b. Executive and organizing ability
- c. Ability to gain and retain confidence and cooperation of fellow workers and public
- d. Skill in analysis of situations and in presentation of material

C. For a staff nutritionist working under close technical supervision of a director of nutrition service.

1. Education *

- a. Successful completion of courses qualifying for a degree as outlined in A1 (a and b).
- b. Field work in a health agency carrying on a nutrition program under the supervision of a qualified nutritionist.

2. Experience *

One year of successful paid experience in the fields listed under B 2 (a or b).

3. Substitutions for experience:

- a. One year of relevant graduate study may be substituted for 1 year of experience. Or if the agency is in a position to provide

* Candidate should have had part of training and experience within 4 years of application

systematic orientation and in-service training plus immediate technical supervision from a nutrition director, previous experience need not be required.

4. Personal qualities:

a. Physical fitness

b. Potentialities for developing—

- (1) Executive and organizing ability
- (2) Skill in analysis of situations and presentation of material
- (3) Ability to gain confidence and co-operation of fellow workers and public

Occurrence of *Shigella* Types in the Military Population of the South- eastern United States— 1943 and 1944

MAJOR CARL T. NELSON, M.C., AUS; SECOND LT. ALFRED
F. BORG, SN.C., AUS; FIRST LT. JOHN SPIZIZEN, SN.C.,
AUS; AND MARGUERITE J. BARNES

Fourth Service Command Medical Laboratory, Fort McPherson, Ga.

IN 1943 and 1944 bacillary dysentery was an important cause of non-effectiveness among troops stationed in the Southeastern United States. Numerous cases occurred in men on field maneuvers but the disease was also relatively common among soldiers and their dependents living under conditions of modern sanitation on or near permanent army installations.* In addition to the several extensive epidemics of bacillary dysentery observed in this population during the two year period, a large number of sporadic or endemic cases were found scattered throughout the region. This communication deals with the incidence and distribution of *Shigella* types in these non-epidemic cases.

Heretofore, information regarding the occurrence of *Shigella* types in the United States has been scanty. The most comprehensive investigations of this nature yet published are those of McGinnes, *et al.*,¹ Hardy, *et al.*,² Mayfield and Gober,³ and Wheeler.⁴ These

authors seem agreed that the so-called Flexner organisms have been the predominant endemic types in this country.

The material presented here represents an analysis of the *Shigella* organisms isolated from 2,119 fecal samples and cultures which were submitted to a large central laboratory for final identification. Only specimens recovered from sporadic cases of acute diarrhea during the years 1943 and 1944 have been included in this study. Cultures obtained from bacteriological surveys of epidemics were excluded in an effort to secure a more accurate index of the relative incidence of *Shigella* types by preventing undue weighting of the data. Since specimens were forwarded to the central laboratory for confirmation regardless of the ease or difficulty in distinguishing the various microorganisms, it is felt that the comparative incidence of *Shigella* types found in this study is probably representative of their relative frequency of occurrence.

METHODS

Fecal specimens submitted to the central laboratory were shipped in

* A large proportion of this population was not native to the Southeast but had been assembled from virtually all regions of the United States. In only a relatively few instances, however, had its members ever lived or traveled outside the continental limits of this country.

TABLE 1

Incidence of Shigella Types Isolated from 2,119 Sporadic Cases of Bacillary Dysentery in the Military Population of the Southeastern United States, 1943-1944

Shigella Type (After Weil et al. ⁷)	Corresponds with		Number of Cultures Identified	Per cent

glycerine-saline preservative. These were cultured on plates of SS (*Shigella-Salmonella*) agar and EMB (eosin-methylene blue) agar by direct inoculation and also after preliminary cultivation in Selenite-F enrichment medium. Suspicious colonies were then picked to Kligler's iron agar slants. Those yielding suggestive or positive Kligler's reactions were studied further by a full series of the customary cultural and biochemical tests. Finally, each culture tentatively classified as a dysentery bacillus was typed serologically by its agglutination reactions in monovalent *Shigella* rabbit antisera. In the early stages of this study the cultures were typed by the tube agglutination method described by Hardy, et al.⁵ Later, when a constant supply of carefully absorbed monovalent rabbit antisera became available,* serological typing was carried out by the slide agglutination technique recommended

by Wheeler.⁶ When previously isolated cultures were sent to the central laboratory, they were first re-streaked on EMB and nutrient agar. Suspicious colonies were picked to Kligler's iron agar and then identified by the same procedures used in the study of fecal specimens.

RESULTS

The relative incidence of the various *Shigella* types found in these cases is shown in Table 1. *Sh. sonnei* was by far the most prevalent organism and was isolated from 1,313, or approximately 62 per cent, of the patients. On the other hand, the so-called Flexner strains of dysentery bacilli (including those assigned to the doubtful types X and Y) were recovered in 706, or only one-third, of the cases. *Sh. dysenteriae* (Shiga) was not encountered and neither the Boyd group (types IX to XIV) nor the Sachs types were found with any frequency. It is interesting that *Sh. alkalescens* was recovered in an appreciable number of cases. Although the pathogenicity of this microorganism

* The absorbed rabbit antisera employed for diagnostic purposes were supplied through the courtesy of Captain Charles V. Seastone, MC, Division of Bacteriology, Army Medical Center, Washington 12, D. C.

for man has often been doubted, the evidence available here indicates that *Sh. alkalescens* is not infrequently isolated from rather severe cases of dysentery.

The geographic distribution of the *Shigella* types recovered from endemic cases of bacillary dysentery in this series is shown in Figure 1. For convenience, the area comprising the Southeastern United States has been divided into 22 districts. The identity of the *Shigella* organisms isolated from the cases in each district is shown in the figure. Generally speaking, these data indicate that the *Shigella* types most frequently found in sporadic cases of dysentery were the ones which

also enjoyed the widest geographic dispersion.

COMMENT

The relative incidence of Flexner and Sonne bacilli found in this study differs considerably from that formerly observed in the United States.¹⁻⁴ The previous reports indicate that the Flexner organisms have been the predominant dysentery bacilli in this country, whereas in these cases *Sh. sonnei* was isolated almost twice as often as all other types combined. It is difficult to say whether or not such findings denote an actual shift in the prevalence of *Shigella* types. As suggested by Weil,⁸ changes in the reported

incidence of various members of the *Shigella* group may be partly the result of improved methods of bacteriological diagnosis. This is particularly true in the case of late lactose fermenters such as *Sonne* bacilli. Nevertheless, the data presented here attest to the widespread occurrence of *Sh. sonnei* and to its importance as a cause of bacillary dysentery in the Southeastern United States.

The geographic distribution of the various *Shigella* types within this region is of some interest. As shown in Figure 1, *Sh. sonnei*, Flexner VI (Boyd 88-Newcastle-Manchester group), and Flexner II (W and WX) tend to be ubiquitous. The other Flexner bacilli, with the exception of type V (Boyd P119), are also well disseminated—as are *Sh. ambigua* (Schmitz) and *Sh. alcalescens*. The remaining members of the group were only rarely encountered and do not seem to be widely distributed in this area at the present time. The diversity of *Shigella* types found in some parts of the Southeastern states is also impressive. East Central Tennessee, the Florida Gulf Coast, and Central North Carolina seem to have been most fertile in this respect during 1943 and 1944.

SUMMARY

An analysis of the *Shigella* types iso-

lated from 2,119 sporadic or non-epidemic cases of bacillary dysentery in the military population of the Southeastern United States during 1943–1944 has been presented. The results show that *Sh. sonnei* was the organism most commonly recovered from these patients. The geographic distribution of the various *Shigella* types within this region was widespread. As might be expected, the varieties of dysentery bacilli most frequently isolated from the endemic cases were also the ones which exhibited the greatest geographic dissemination.

Incidence of Certain Biological Characteristics among "Food Poisoning" Staphylococci

HARRY A. FELDMAN, MAJOR, MC, AUS *

THE final identification of a given staphylococcal strain as the causative agent of a food poisoning outbreak is usually dependent upon its ability to produce enterotoxin as measured by one of the cat tests.^{1, 2} As a result of this requirement the large control laboratory is frequently faced with the dilemma of deciding upon how many of the staphylococcal colonies isolated from the materials submitted from a given outbreak are to be subjected to cat testing. This problem would be simplified if a reasonably accurate screening procedure were available.

Although Stritar and Jordan³ have demonstrated that no one staphylococcus is responsible for food poisoning, it was considered that the results obtained by the use of a slightly different combination of tests in a series of 109 staphylococcal strains isolated from food poisoning material might be of interest. Twenty-two of the organisms were submitted as cultures; the remainder were isolated directly from food specimens which had been forwarded to this laboratory for study.

Methods—Following initial isolation (or purification) on tryptose agar, several staphylococcal colonies were selected from each plate for complete study. Pigmentary groupings were determined after cultivation on plain

and blood (citrated horse or sheep) tryptose agar for a maximum period of 48 hours. Hemolytic properties were determined after incubation for 24 hours on the same blood agar medium. Coagulase activity was tested in a 1:4 dilution of human plasma as described by Chapman, *et al.*⁴ Mannite fermentation was studied in peptone water containing 0.5 per cent mannite⁵; the maximum period of observation was 48 hours. The method of Dolman and coworkers as cited by Koser⁶ was employed for the preparation of material for the enterotoxin test. When cats were available the intravenous method of Davison, Dack, and Cary¹ was employed, whereas when it was necessary to use young kittens the intraperitoneal method of Dolman, Wilson, and Cockcroft² was selected. The majority of the tests were performed by the intravenous cat method.

No enteric pathogens were isolated from any of the source materials used for this report.

Data and Discussion—The incidences of the various characteristics are summarized in Table 1. It will be noted that while 27 of 93 (29 per cent) strains tested yielded positive enterotoxin tests, 23 of these occurred among golden strains. Although only 9 of the organisms fermented mannite, 21 were hemolytic and 21 produced coagulase. Table 2 concerns itself with a break-

Totals	27	14	13	3	22	18	9

down of the enterotoxin positive strains. Seventy-eight per cent of the aureus strains were coagulase-positive and 61 per cent were hemolytic, but only 14 per cent fermented mannite. This is in contradistinction to the 4 albus enterotoxin producers in which none of these characteristics were demonstrable. While the two studies are not wholly comparable, these figures confirm Stritar and Jordan's³ earlier findings, that if enterotoxin production is used as the criterion of food poisoning capability none of the other biological characteristics occurs with sufficient regularity to be pathognomonic of such ability. However, our data do suggest the generalization that golden, coagulase-positive, hemolytic staphylococci isolated from suspected food poisoning sources are likely to be enterotoxin producers; consequently, determination of these characteristics may be employed as a screening procedure in situations where animal testing must be conducted on a limited scale. Such screening can be undertaken only with the realization that a number of cat-positive specimens will be missed. In such situations it might be practical to seed all staphylococci isolated from a

single food (or all specimens) in one flask of the enterotoxin medium and then to use the common filtrate in a small group of animals.

TABLE 3

Sources of Twenty-seven Enterotoxin Positive Staphylococcal Strains

Peas	1	0
Fish	2	0
Wieners	1	0
Unknown	2	0
Totals	23	4

* Submitted in this form, food source unknown.

Table 3 indicates the various sources from which the enterotoxin strains were isolated. The group of vomitus specimens yielded rather surprising results. They all came from a single outbreak and had the same characteristics: hemolytic, coagulase-positive and mannite-negative. The organisms were isolated in almost pure culture so that this material suggests itself as a

potentially good source of the etiological agent of an outbreak. Two of the specimens also contained citreus colonies, but these were negative in all other respects.

SUMMARY AND CONCLUSIONS

1. Of 109 strains of staphylococci isolated from foods and human vomitus during bacteriologic studies of food poisoning outbreaks, 27 strains produced enterotoxin as measured by one of the cat tests. Twenty-three of the 27 were classified as *Staph. aureus* and 4 as *Staph. albus*. Of the *Staph. aureus* strains 78 per cent were coagulase-positive and 61 per cent hemolytic, while 14 per cent fermented mannite. The *Staph. albus* group had none of these characteristics.

2. Those staphylococcal strains which produced coagulase, hemolysin, and golden pigment were more likely to produce enterotoxin, but this combination of characteristics did not occur with sufficient regularity to replace the cat test.

3. Seven enterotoxin positive strains were isolated from human vomitus while the remaining 20 came from a multiplicity of foods.

4. Under the conditions of this study mannite fermentation appears to be a poor, unreliable indicator of potential enterotoxin production by staphylococci.

Hawaii Adopts Bread and Flour Enrichment Program

The Legislature of the Territory of Hawaii, according to Dr. C. L. Wilbar, Jr., the President of the Board of Health, at its last session, passed an act requiring the enrichment of bread and flour, which became effective May 8, 1945.

This act makes it unlawful for any person to manufacture, mix, compound, sell or offer for sale flour, white bread, or rolls for human consumption in the Territory unless they contain standard amounts of thiamine, riboflavin,

niacin or niacin-amide and iron. The standards embodied in this legislation are in accord with those recommended by the Food and Nutrition Board of the National Research Council and the Federal Security Agency, with the exception that the Council's optional standard for vitamin D was not adopted. However, a minimum of 500 milligrams and a maximum of 1,500 milligrams of calcium per pound have been adopted for enriched self-rising flour.

A New Statement of School Health Policies

CHARLES C. WILSON, M.D., F.A.P.H.A.

Chairman, National Committee on School Health Policies; and Professor of Health and Physical Education, Teachers College, Columbia University, New York, N. Y.

A HEALTHIER America waits upon and depends upon the universal adoption of sound school health policies. The National Committee on School Health Policies, formed in 1945 by the National Conference for Co-operation in Health Education, faced squarely the problem of stating definitely and clearly policies under which school health programs might be maintained and improved in thousands of different school situations. The broad scope of its conclusions and suggestions can be gleaned from the range of the committee's recommendations. It is recommended that all schools:

"Organize a school health council;

"Make provision for healthier school living by raising their standards of inspection for safety and sanitation, by employing more understanding and emotionally stable teachers, by paying more attention to the health of school personnel, and even by serving better food;

"Improve the quality of health and safety instruction by according more time, securing better-qualified teachers, granting more scholastic credit and providing more adequate teaching materials;

"Clarify and sharpen their programs for the prevention and control of communicable diseases and avoidable accidents;

"Institute wider programs of health counseling, including keener teacher observation, more frequent screening tests, and more useful medical and psychological examinations;

"Enforce more intelligent precautions in physical education and athletic programs;

"Identify sooner and provide more sensibly for handicapped children;

"Provide in-service education to help teachers to understand the health problems of children;

"Participate in programs of parent and community health education; and

"Seek qualified medical advisors, nurses, health educators, and other necessary specialized health personnel."

While these recommendations represent current thinking, the idea of a statement of school health policies is not new. More than five years ago the Maternal and Child Health Section of the American Public Health Association appointed a committee* to prepare a statement of school health policies. Following the preparation of a preliminary report, that committee suggested that its report be submitted to a number of other groups concerned with school health programs. This suggestion was approved and acted upon. These other groups suggested changes and improvements which were incorporated into the preliminary material, and the final report was published in 1940 under the name of eight different national organizations. It was widely used as a guide and for discussion purposes.

Now a 1945 revision of *Suggested*

* Members of that committee were Harold H. Mitchell, M.D., Mary E. Chayer, R.N., and Charles C. Wilson, M.D.

School Health Policies is available* for guidance of all concerned with school health programs. Although based on the original report, the present edition has been so completely rewritten and rearranged that it is practically a new statement.

Like its predecessor, the 1945 edition of *Suggested School Health Policies* was produced by the coöperative efforts of representatives of many professional groups; it is an integration of the viewpoints of educators, physicians, nurses, and public health specialists. The following is a list of those who worked diligently in preparing the 1945 edition, together with the names of the organizations which nominated them:

- W. E. Ayling, M.D., American School Health Association
- W. W. Bauer, M.D., American Medical Association
- Edward S. Evenden, Ph.D., American Association of Teachers Colleges
- Raymond A. Green, M.A., Secondary School Principals Association
- W. H. Lemmel, Ed.D., American Association of School Administrators
- S. S. Lifson, M.A., U. S. Public Health Service
- Ben Miller, Ph.D., American Association for Health, Physical Education and Recreation
- Harold H. Mitchell, M.D., American Academy of Pediatrics
- Dorothy Nyswander, Ph.D., American Public Health Association
- Thurman B. Rice, M.D., Joint Committee on Health Problems in Education of the N.E.A. and A.M.A.
- Justus J. Schifferers, Health Education Council, New York (*Secretary*)
- Maycie Southall, Ph.D., Educational Policies Commission
- Frank Stafford, M.A., U. S. Office of Education
- George M. Wheatley, M.D., U. S. Children's Bureau
- Alberta B. Wilson, R.N., National Organization for Public Health Nursing
- Charles C. Wilson, M.D. (*Chairman*)
- J. M. Wisan, D.D.S., American Dental Association

Upon the Secretary of the committee, Justus J. Schifferers, fell the responsi-

bility for arranging and editing the report. It was my privilege to act as Chairman of the committee.

Suggested School Health Policies recognizes fully that the efforts of health departments and education departments, as well as all other community groups, must be closely coordinated in order that the benefits of modern knowledge of health and of disease prevention may be extended to all children. It suggests that a health committee or health council be organized in each school and each school system and that such groups participate in community health councils. It suggests that all community resources be made available to meet the health needs of students, and that community planning should, if necessary, lead to the development of additional resources.

The suggested policies regarding health and safety instruction recognize the important changes in this part of the school curriculum, particularly at the secondary school level where specific health courses are recommended. Health courses should be taught by teachers with special preparation and certification in health education. A variety of teaching methods should be used.

The section of the report dealing with Services for Health Protection and Improvement suggests policies relating to the care of emergencies, the prevention and control of communicable disease, and health counseling. Health counseling is described as "the planned coöperative effort on the part of teachers, nurses, physicians, psychologists, dentists, and others to discover the health needs and health problems of students and to help them and their families find ways of meeting the needs and solving the problems." Specific suggestions are offered regarding the determination of health needs and problems; the interpretation of these needs to students, parents, and teachers; and

* Reprints of the complete report can be obtained from the American Public Health Association (25¢).

to meeting the needs through community resources.

That education is for *all* children is one viewpoint expressed in the policies report. Recommendations are made for the care and education of both physically and mentally handicapped pupils.

As significant as any policy it proposes is the demonstration by the National Committee on School Health Policies that there are no insurmountable barriers to the coöperative efforts of different professional groups. The committee agreed unanimously on the

policies suggested. A spirit of friendly coöperation and of mutual interest prevailed at all times. This type of interprofessional coöperation may well be fostered by state and local groups interested in protecting and improving the health of children.

Members of the National Committee on School Health Policies hope that its report will be used for discussion by numerous groups interested in the health of school children, and that each of the national organizations represented on the committee will in time officially approve the report.

THE LIFE BLOOD

IN an earlier issue of the *Journal*,¹ we have discussed the possibilities of the use of gamma globulin in the control of measles. Gamma globulin is, however, but one of many important elements in the marvellously adjusted fluid which flows out through the arteries to all the tissues of the body. The ancients were not far wrong in visualizing the heart as a symbol of the force which drives the human organism and the blood as the very essence of human life.

For this number of the *Journal*, we have asked Dr. C. A. Janeway to prepare a comprehensive review of the broad outlines of the subject of the "Blood and Blood Derivatives"—a topic which has been brought for the first time into the field of concrete, large-scale, application by the experiences of the war. Dr. Janeway surveys the wide possibilities of the use of whole blood, of resuspended red cells, of plasma, of fibrinogen and thrombin products, of gamma globulin, of isohemagglutinins, of serum albumin, and other fractions of plasma in the prevention and the treatment of disease. He points out the hazards to be avoided from transmission of syphilis and malaria, and serum jaundice, from the presence of antigens and antianaphylactic bodies and from the Rh factor.

Above all, he emphasizes the fact that the processes of procurement, processing, and distribution of blood and blood derivatives involve administrative problems of major magnitude. He cites the progress made in Michigan and North Dakota and the plans of Massachusetts. Whatever rôle may be played in different localities by the American Red Cross, the local hospital and the state or local health department, the problem is clearly one which, as the lawyers say, "is vested with the public interest." The health officer represents that public interest, and this review should be of the greatest value to him in dealing with what Dr. Janeway rightly describes as "A New Public Health Field."

A LAWYER SPEAKS TO DOCTORS

ON November 19, 1945, President Truman delivered to Congress a message on a national health program which marks an important milestone on the long road toward public health. It includes the five basic elements which have entered into all informed discussions of this subject: provision of hospitals and related facilities for areas now lacking service of this kind; expansion of public health services, particularly those related to maternity and infancy; advancement of medical education and research; a comprehensive plan of prepayment for medical care; and extension of social security to cover the hazards of sickness and disability. It is a bold and statesmanlike document—a clarion call to action.

The exact form of legislation to carry out these purposes will come before the Congress and the people during succeeding months. Discussions of details must await their concrete formulations. As a preparation for reasonable discussion, we urge preliminary study of an article presented in *Public Health Reports* for January 5, 1945. If your volume has not been bound as yet, dig this number out of your files. Take it with you on a train or in a bus and read an address by Wendell Berge, Assistant Attorney General of the United States on "Justice and the Future of Medicine," delivered before the American Urological Association. It is one of the clearest and fairest analyses of the basic principles which should govern our planning for medical care which have yet appeared in print.

Mr. Berge makes three points of major importance. The first of these is his emphasis on the fact that medical service as an actuality involves social and economic as well as medical factors. He recognizes that this problem is "unusually baffling. For it is only the exceptional person who has experienced all the arts—technical, economic, cultural—which converge in it. A beginning of understanding lies in a recognition of a distinction between the technology of medicine and its organization. By technology I mean all of those arts of diagnosis, therapeutics, surgery, radiology, dentistry, and the like, which constitute the profession of medicine. By organization I mean all of the arrangements, social and economic, by which medical service is made available. It is idle to dispute as to which is the more important; for there must be a medicine to practice, and there must be arrangements for bringing physician and patient together. It is no veiled mystery as to which is the more backward. In the advance of the art of medicine, you have done a brilliant job. In the face of this advance it is all the more tragic that progress in the organization of medicine has lagged and, because of this lag, the nation has not had the full benefit of your superlative performance."

With regard to the problems of organization of medical service—as distinct from the practice of the medical arts—Mr. Berge points out that "as a group, physicians have been little exposed to the discipline of the social sciences, and social organization is as intricate and as full of mysteries as the art of medicine itself. So when I hear a physician speaking about the organization of medicine in a tone of doctrinaire finality, I cannot fail to remark the contrast with the courageous and humble search for truth displayed in his own work. And when I hear the question put as a choice between private practice and socialized medicine, I cannot escape noting a confusion and dogmatism strikingly different from the scientific approach. As for the 'either or' of private practice and

socialized medicine, there is no such question. There are a myriad of schemes under which the doctor and the patient may be brought together—not a choice between just two.” There is “no such question as private practice versus socialized medicine. For practice is never private and all medicine has a social function.”

Mr. Berge deals effectively with the claim that no other system than individual financially-competitive medical service can safeguard quality of medical care, an essentially intimate personal relation between physician and patient and the morale and initiative of the physician. “Such values,” he says, “depend upon no one single way of organizing medicine. To say that a doctor will give his utmost if he acts as his own business agent, and that his incentive will be stifled if he receives a salary, is not borne out by experience. The time was when the great scientific advance was the work of the solo inventor. Today the most creative of all work, the progress of science and the useful arts, is the product of men on salary. In the larger offices the great mass of lawyers now work on salary and work as hard and as heroically as the youngster who used to flaunt his own shingle in the breeze. It is true that the chance to become a partner is an incentive, but I would not rank it overly high, for work equally as good is done by the lawyers in the Government, where no such opportunity exists. In our institutions of higher learning, research as well as teaching falls to salaried employees and there you will observe an interest, excitement, devotion to duty, an urge to be up and doing. To return to medicine, how many thousands of our best doctors are today giving their all without stint in the service of the Army and the Navy?

“Ambition, security, income are necessary things. They have in every age and among the most varied conditions of society driven men to accomplishment. If I were a youngster, I would rather leave the series of judgments which shape my career to men of my own profession than attempt to get ahead by translating my skills into the art of winning and holding patients.”

Mr. Berge's third emphasis is on the inevitability of changes in the present system of medical services and on the importance of medical participation in planning such changes. “The arts of medicine,” he tells us “have advanced; the importance of medicine has been enhanced; it has become a necessity to the people and an essential in the operation of the industrial system. It has outgrown the organization into which, in days of petty trade, it was cast. The demand is for a vaster, more comprehensive, more reliable medical service. If an instrument of the common health can be provided on terms the people can afford, the people will rejoice. If you do not help them to do it, the people will seize upon whatever agencies are at hand as a help in time of need, for the universal demand that the common health be served cannot much longer be stayed.

“A new medical order is inevitable. Whether we shall cling to the old order or create a new one is not the question. The swift course of events has decreed that there can be no turning back. The question is rather what sort of a medical order it is going to be and whether it is the best which wisdom and knowledge can contrive. Like every promising venture, it has its hazards. Is it to be shaped by the best understanding which law, medicine, and the social studies can bring to it? Or is it to be constructed by amateurs in ignorance but with good intentions?”

He makes the following final plea to the medical profession: “I can hand you no ready-made medical order on a silver platter. If I could, it would do you

no good. I can only suggest to you, whose minds have long been busied with the subject, some reflections of a man of another profession. And I am positive that a service adequate to the times cannot be brought into being without the doctors' creative participation. As doctors and patients we face a crisis, and my appeal is to the ancient wisdom of the profession. The ends of medicine remain unchanged; ways and means must be found to adapt its practice to the conditions of present-day society. A new organization must be created that an ancient mission be not lost, that once again medicine shall be available to all in need and charges shall be graduated in accordance with ability to pay.

"An instrument of the common health such as never before has been offered to a people is within our reach. This is no time for petty doubts and timid moves. In the face of a national challenge we must, as one of our great jurists said of the law, let our minds be bold."

SAFE AT HOME?

HOME accidents represent the ninth most important cause of deaths in the United States. During the past five years more than 150,000 persons have died as a result of such accidents. The number of these deaths annually in this period has varied from a low of 30,000 in 1941 to a high of 33,500 in 1943.

The present indications are that there will be no marked change in the number of home accident fatalities this year. The National Safety Council estimates that there were 23,300 such deaths during the first nine months of 1945 as compared with 23,000 for the same period for 1944, an increase of approximately 1 per cent.

Although reliable home accident morbidity figures are not available because of the absence of any required reporting procedure, it is reasonable to suppose that the frequency of non-fatal disabling injuries, estimated at 4,800,000 in 1944, follows the same general pattern indicated by mortality figures.

Viewed in relation to its effect on the nation's mortality and morbidity experience, the prevention of home accidents can therefore be considered as one of our major public health problems as pointed out by W. Graham Cole at the December meeting of the Public Health Association of New York City.* It is a problem which requires careful fundamental study and the development of effective control procedures. Most home accidents are preventable, but procedures for their control must contemplate not only the correction of environmental conditions but a change in individual attitudes and the development of safe habits and behavior characteristics.

The responsibility for leadership in developing and applying control procedures for the prevention of home accidents rests largely in the public health field and upon the official public health agency. It is important, therefore, that the American Public Health Association through its Committee on Administrative Practice has set up a Subcommittee on Accident Prevention. As a preliminary step this subcommittee undertook a study of home safety activities conducted on the state level. Based on this study, a summary of the state-wide safety activities being conducted in New York, Minnesota, New Jersey, Illinois, and Kansas, was prepared and printed in the January, 1944, issue of "The Spotlight." Subse-

* To be published

quently the subcommittee developed a general program statement entitled "Accident Prevention—An Essential Public Health Service" and an outline, "Suggested Home Safety Activities—For Consideration of Local Health Departments." This material was printed in the March, 1945, issue of the *American Journal of Public Health*. Reprints of it, together with copies of a leaflet entitled "Get the Facts about Accidents," prepared by the National Safety Council, have been distributed to state, county, and city health departments.

The subcommittee in its program statement calls attention to the seriousness of the entire accident problem, pointing out that all types of accidents taken together represent the fifth cause of death in the United States. The subcommittee recognizes the vital part that organized accident prevention activities has played in the prevention of industrial, traffic, and other public accidents. It notes, however, that insufficient organized attention has been given to the prevention of home accidents, and states its belief that this latter field represents one of the major untilled fields of public health.

Of considerable significance is the fact that the program recommended by the Committee on Accident Prevention was published within a few months of the publication of the preliminary reports developed by the A.P.H.A. Committee on Hygiene of Housing. There is a definite correlation of interest between these two projects. Although statistics indicate that not all home accidents can be charged to improper environment, many home accidents do occur as a result of unfavorable housing conditions. Local studies in the field of hygiene of housing and in the field of home safety can be correlated effectively.

That home accident prevention is receiving increased recognition in the public health field is evidenced by the responses from several health officers who have commented on the subcommittee's program.

For example, the Health Department of Madison, Wis., publishes a pamphlet *Accidental Deaths*, which is a well annotated statistical review of the problem as it affects the City of Madison. The Health Officer indicates that he is fully appreciative of the fact that home accidents constitute a public health problem, and has established a program which includes the distribution of material on the subject.

The Health Officer of Pasadena, Calif., writes that his Department is actively interested in incorporating home accident prevention work in its program and has published a pamphlet which develops the theme, "Accident Prevention and Public Health."

The Health Officer of Omaha, Nebr., indicates his Department's willingness to cooperate in home accident prevention activities, and the Bureau of Vital Statistics of the Honolulu Board of Health advises that a Committee on Accident Prevention has been organized by the board.

It is interesting to note that one of the most active areas for home accident prevention programs is in Chattanooga, Tenn. The Tennessee Valley Authority states that its activities include a home accident survey in city schools. An analysis of these accidents is made on a district basis. The information is posted in schools so that each school may know the accident experience in its particular district. A recording system has been developed and is being operated by the Junior Red Cross in conjunction with the school systems. Home Accident courses are being conducted in the community, and the Junior courses are given in connection with the school curriculum. A series of leaflets on home safety has been distributed among T.V.A. employees.

As an aid in coordinating existing effective home safety activities of health agencies and other groups, and to stimulate the conduct of additional activities in this field, the National Safety Council and the American Red Cross, with the cooperation of the American Public Health Association and other agencies, is developing a nation-wide home safety educational program.

The prevention of home accidents represents a responsibility and an opportunity for state, county, and city health departments, as well as for nonofficial health agencies interested in the reduction of mortality and morbidity. Experience is showing that effective activities can be developed to meet this responsibility and to render an additional and necessary public health service, in cooperation with associated community safety organizations.

EMPLOYMENT AND PLACEMENT SERVICE

The American Public Health Association announces an expansion of the Employment Service which has become a Counseling and Placement Service for public health workers and employers. This project which is primarily for the service of veterans has been made possible through the cooperation of the United States Public Health Service.

Counseling and guidance services for the various public health specialties are available to candidates through well trained staff consultants. Besides this function the Counseling and Placement Service establishes lines of contact between employers and candidates. It thus serves as a clearing house without recommending or sponsoring candidates or positions.

The facilities of the employment page are open to members free of charge.

A PROUD RECORD

The *Journal* has had occasions to mark several anniversaries of late but there is none of which it is prouder than the twenty year record of Raymond S. Patterson as editor, compiler, judge, analyst and commentator of the department known (at present) as "A Selected Public Health Bibliography with Annotations."

From the welter of published material dealing with health, probably some million words yearly, Dr. Patterson culls each month some dozen or more items worthy of note, highlights them with provocative headings, and in a few lines pins down something about the report, leaflet, or article which makes it worth reading. The technique is so airy, gossipy, and casual, one forgets the extremely careful and thoughtful reading, backed by a wide knowledge of the health field, on which the selections are based. The department is unique; the needling of the reader's interest is expert, painless, even pleasant. To remember that this is the work of one individual is remarkable testimony to Dr. Patterson's catholicity of interest, rare judgment, and skillful pen. The first two decades were the hardest, Dr. Patterson. Your grateful readers know how smoothly you will handle the products of the next twenty!

WHO ARE THE VOCAL ANTIVIVISECTIONISTS?

Dr. Paul B. Brooks in his column, "Dr. Jones Says," in the November 12 and 19, 1945, *Health News* of the New York State Department of Health, philosophizes on the current antivivisectionist revival thus:

Well, the "antivivisectionists"—from the barrage of propaganda that's been coming

over recently, it looks like they're getting ready for another "break-through" attempt when the Legislature meets again: to get a law prohibiting the use of dogs for scientific experiments. It's hard for most people to realize but, if I'm any judge, that represents a greater threat to human welfare, health and safety than the break-through the Germans made over there in Belgium last December.

Being a "dog lover" myself I can understand their reactions. They're crusading—most of 'em—because they've got 'emselfes worked up to a point where, to them, the comfort and happiness of dogs is the most important thing in the world. A few of 'em, of course—they're doing it because they're well paid for it. And I've got a feeling they're the ones, principally, that're keeping this movement going. I can understand that too: wanting to keep a good job. . . .

Most any of 'em, though, if they got sick themselves, I'll gamble they wouldn't call an "antivivisectionist" doctor (and there are a few of 'em, around the country). They'd want one that used his head—not his emotions. And what they had—if it happened to be diabetes, we'll say, and insulin'd save their lives, the fact that they had to use dogs in developing it—that wouldn't worry 'em any. Their lives'd be worth more to 'em than the lives of any number of dogs. Other people's lives—maybe that's different. . . .

* * * * *

We were speaking, here recently, about the "antivivisectionists": the probability they'd try again to get a bill through prohibiting the use of dogs for scientific experiments. They've been trying for years but the legislature, when it came to people versus pups, they've always put human life and health first. But these aggressive minorities—they're usually well organized for putting on pressure and the legislature—well, if there was equally effective pressure on the other side, at least it'd relieve the strain.

But one trouble in the past, the opposition to this stuff—it's been, mostly, the doctors and other scientific people. They've pointed out what a setback it'd be to medical science if the use of dogs was prohibited. But it's been the human side of it they've stressed. And I suspect the general impression may have been that dog owner's as a whole, favored the prohibition.

But when you stop to think of it "dog owners, as a whole" ought to be right up in the front line, opposing that kind of legislation. The good canines—pets, hunters, workers, show-dogs they're benefiting from experiments made on dogs, the same as the humans are.

Canine distemper—I s'pose that's probably killed more dogs than any other disease. Today most of the valuable dogs are protected against it by vaccination. It was by experimental work with dogs that the vaccine was developed. Rabies—the worst disease a dog can have and one he's liable to be exposed to: the vaccine that protects against that is the result of experiments on dogs.

"Black tongue" (the same as pellagra in humans) feeding experiments on dogs that had it led to the discovery of its cause and cure in dogs and humans, both. It was a matter of supplying a vitamin they lacked. And the prepared dog-foods—what the dog needs for his nutrition—it's been determined by experimenting with dogs.

Yes, sir. As the owner of a pedigreed dog and a contributing member of a humane society, I'm opposed to any legislation that's against the interests of dogs "as a whole"—to say nothing of humans.

WELCOME TO "CANADA'S HEALTH & WELFARE"

The October, 1945, number of *Canada's Health & Welfare* is Vol. 1, No. 1 of this new monthly Bulletin of the Canadian Department of National Health and Welfare. Aside from its general information on health and welfare matters in Canada, it has monthly Personality Sketches, Global Report, and Book Review columns. In the first issue Dr. John T. Phair, Deputy Minister of Health and Hospitals for the Province of Ontario and Charter Fellow of the A.P.H.A., is the subject of the personality sketch; in the second issue Dr. Haven Emerson's *Local Health Units for the National* has the lead review. The two global report columns discuss respectively the United Kingdom Family Allowances Act and The First Ten Years of the United States Social Security Act. Our congratulations to the Honorable Brooke Claxton, the Minister of National

Health and Welfare, and his staff on these first issues and their "one world" character.

GROWING OLD GRACEFULLY

It's an old story that by 1950 the United States will have 50,000,000 oldsters of over 45. Two items from widely separated parts of the country suggest a growing awareness of the changes this development is making in social and health programs. The Welfare Federation of Cleveland in mid-November opened a month long exhibition entitled "Live Long and Like It" in the Cleveland Health Museum. Intriguing subtitles are, "The Four B's—Baldness, Bifocals, Bridges, and Bulges" and "How Grandma Helped on the Home Front." A special feature of the exhibit was "The Golden Age Hobby Show."

The other item comes from Cooper Union in New York. This fine old College of the people announced for the current winter season a series of lectures on Aging Successfully, by George Lawton, the Director of the Old Age Counselling Bureau. Although designed primarily "for those in the later maturity age range," even the young are invited to get an understanding of parents, grandparents, and older business associates who are often their bosses. "You Can Teach an Old Dog New Tricks," and "Grandma Made Johnny Delinquent," are among the lecture titles.

SPECIAL EXHIBIT AT YALE MEDICAL LIBRARY

Credit Lines is indebted to *Science* of September 21, 1945, for the following: "The Yale Medical Library has now on display a special exhibit arranged in recognition of the distinguished services of Dr. Charles-Edward Amory Winslow, senior member of the faculty of the Yale School of Medicine, who retired at the end of June. Since Dr.

Winslow has for many years conducted séminars on the history of personal hygiene and the public health movement, the first part of the exhibit is devoted to early writings on hygiene, beginning with Galen and his concept of the 'Non-Naturals' in relation to health. Five display cases are devoted to Dr. Winslow's writings. His contributions to the historical and biographical phases of the public health movement occupy a separate display case. His latest monograph, entitled 'The Conquest of Epidemic Disease,' and a selection of his many monographs and papers on ventilation and air conditioning are displayed. The first volumes of the *Journal of Bacteriology* and the *American Journal of Public Health*, of which Dr. Winslow has been editor, the first since its inception in 1916, and the other since April, 1944, are also on view."

NEWS IN NOISE CONTROL

The October 15 *News Bulletin* of the National Noise Abatement Council announces 1945 Achievement Award plaques to five cities for outstanding civic accomplishment in the abatement of needless noise: Chicago among cities with populations of 500,000 or more; Rochester, N. Y., among those of 250,000 to 500,000 population; Salt Lake City, among those of 100,000 to \$250,000; Little Rock, among those under 100,000; and Memphis, the Grand National Award Winner. With this issue of the *Bulletin* was enclosed a reprint from the *American Journal of Public Health* of March, 1944, on "The Problem of Industrial Noise" by Paul E. Sabine, Director, Riverbank Laboratories, Geneva, Ill.

INDUSTRIAL HYGIENE INSTITUTE IN DETROIT

The Detroit Industrial Safety Council sends us the program of its two day Institute on Industrial Health, Hygiene,

and Nursing held in November, 1945, with the coöperation of both the Michigan and Detroit Health Departments, the Michigan and Wayne County Medical Societies, as well as the Michigan Association of Industrial Physicians and Surgeons, the Michigan Industrial Hygiene Association, and the Detroit Industrial Nurses Association. Speakers included various technical experts from both state and city departments, the University of Michigan School of Public Health, and other universities, as well as physicians, nurses, and engineers from the industrial plants of Detroit.

WELCOME TO "THE PUBLIC AND EDUCATION"

The National Education Association sends us No. 1, Vol. 1, of *The Public and Education* whose purpose is "to present directly to influential leaders in all phases of American life significant information concerning the rôle of education in our country." This first issue is a four page leaflet well printed and interestingly illustrated. The publication may be secured free of charge from the National Education Association, 1201 Sixteenth St., N.W., Washington 6, D. C.

WISCONSIN COÖPERATIVE SCHOOL HEALTH PROGRAM

One of the briefest and best descriptions of a school health program designed to integrate school health with the whole school curriculum, appears in the annual report (1944-1945) to the W. K. Kellogg Foundation of the Wisconsin State Department of Public Instruction, State Board of Health, and coöperating agencies. The report summarizes the progress of the Wisconsin Coöperative School Health Program. We quote: To include in every school provision for

1. Adequate health instruction at each grade level;

2. A healthful physical, mental, emotional and social school environment;
3. Health services to determine the health status of each child at certain intervals, to adjust the school program of the child to meet his needs, and, if possible, to seek correction of remediable defects through the family physician and dentist;
4. Prevention and control of disease among school children;
5. Prevention of accidents and care of emergency conditions at school;
6. Special education for handicapped children;
7. Inservice training and supervision of teachers; and
8. Interpretation of the school health program to the home.

The whole report, with the year's accomplishments made possible by an unusual number of cooperating agencies, is well worth reading. Copies are obtainable from the State Department of Public Instruction, Madison, Wis.

AN ENTERPRISING NEWS LETTER FROM GEORGIA

A *News Letter* sponsored by the Engineering Section of the Georgia Public Health Association has completed its first year with Volume 1, No. 5. This is a well written and very newsy sheet digesting the activities and interests of those in environmental sanitation in Georgia and largely made up of personals which must serve to develop an *esprit d'corps*. The Secretary of the Georgia Public Health Association is Louva G. Lenert of the State Department of Health, Atlanta 3, Ga.

"THE WELFARE POST" OF MISSOURI

Inspired by the new Missouri Constitution that will go into effect in 1946, the Missouri Welfare League, whose purposes are "prevention of delinquency and reduction of crime" publishes *The Welfare Post* in Springfield, Mo. The September, 1945, issue, Vol. 1, No. 1, deals with a variety of health and welfare problems of the state and describes several of Springfield's colleges

and other social agencies. It also summarizes the six lectures on "State Health and Welfare Organization under the Missouri Constitution," given last winter under the auspices of the Washington University School of Social Work and the Missouri Association for Social Welfare, as well as other citizen activities leading to the formation of a plan for the new Department of Health and Welfare designed to give the best possible service in the field of public health, public welfare, mental hygiene, and corrections. The new Constitution writes a joint health and welfare department into the law of the state.

TWO REPORTS ON COMMUNITY SERVICES

Lining up home town resources for better living, including intelligent service to the veteran, is the subject of two brief reports appearing almost simultaneously from a group of knowledgeable persons.

The Home Town Job—a report on community services for veterans by the National Committee on Service to Veterans, under the auspices of the National Social Work Council, summarizes what home towns are doing for veterans and how to get the job done right. It is an informative, clear-cut statement, emphasizing skilled leadership and cooperative effort as essentials to success. The successful program of several cities is described.

The Road to Community Reorganization tackles home town problems on a wider front, "the community."

The recommendations of this report are worth careful study, especially those that relate to the establishment of a new federal department headed by a Cabinet secretary, and might well be a subject for discussion at the same meeting at which the Gunn-Platt report on *Voluntary Health Agencies* is reviewed.

Copies of the former report are available from the National Social Work

Council, 1790 Broadway, New York 19, N. Y., 10 cents each; 6 cents plus postage for 100 or more copies.

The second report may be secured without charge from the Woman's Foundation, 10 East 40th Street, New York 16, N. Y.

"CHALLENGE TO COMMUNITY ACTION"

From the Social Protection Division, Office of Community War Services in the Federal Security Agency in Washington 25, D. C., comes a 76 page booklet—*Challenge to Community Action*. This is the record of five years' progress in social protection and the lessons learned in some 1,900 communities leading to a pattern for action in the control of venereal disease infec-

tions. It should be read by every health worker, for three good reasons: it supplies the most recent information about the weapons with which we fight venereal disease—the drugs, law, education and social treatment; it gives the most approved line of attack—our battle strategy as it were, through the use of community agencies, and it tells where to get reinforcements in a generous list of interested national agencies, books, leaflets, reprints, films, and posters. "The problems," states this booklet, "are bigger than they were in 1919, but we are much better prepared to face them"—thanks in part to this utterly frank and thorough analysis of the strength of our enemy.

Copies are free.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

All books reviewed in these columns may be purchased through the Book Service.

Injury and Death of Bacteria by Chemical Agents—*By Otto Rahn. Normandy, Mo.: Biodynamica, 1945. 183 pp. Price, \$3.60.*

The author presents a very interesting discussion on survivor curves of unicellular and multicellular organisms. Explanations of the differences of the curves are presented by presentation of survivor curves of various multicellular and unicellular organisms. The author claims that the difference in the order of death is due to the fact that, in the case of bacteria, when one cell dies, the individual is dead, whereas in the multicellular organism the death of one cell does not necessarily cause death.

A very excellent presentation of the mode of action of disinfectants and antiseptics is given. The limitations of the F.D.A. method of testing disinfectants are discussed, together with other suggested methods. A new method of testing is suggested.

The author has brought together scattered facts about disinfectants and antiseptics which will aid considerably in lessening the confusion that exists in this important field.

W. L. MALLMANN

An Experiment in the Psychiatric Treatment of Promiscuous Girls—*By Ernest G. Lyon, M.D., Helen M. Jambor, Hazel G. Corrigan and Katharine P. Bradway, Ph.D. San Francisco: San Francisco Dept. of Public Health, 1945. 68 pp. Free to subscribers of the U. S. Public Health Service Journal.*

Those who have awaited with interest

the reports from the San Francisco project coöperatively set up through federal, state, and city auspices, and with the active coöperation of state and local voluntary agencies, will want to read this report of the experience relating to promiscuity among 365 girls and women.

This study confirms the opinion that promiscuity "is individually motivated and can be understood and treated only on an individual basis."

The authors believe that psychiatric facilities may be used fruitfully in connection with a venereal disease clinic to decrease or eliminate promiscuity among a selected group who voluntarily make use of treatment service.

REGINALD M. ATWATER

The Nurse and the Law—*By Gene Harrison, A.B., R.N. Philadelphia: Davis, 1945. 353 pp. Price, \$3.00.*

"The nurse cannot be a lawyer any more than she can be a doctor . . . However, just as she is obligated to know many things the application of which is the prerogative of the physician, just so may the well prepared nurse be expected to know many things the application of which belongs to the lawyer and the Court."

Public health nurses would not take exception to the words of Dr. L. E. Dickson who writes the introduction to this book, and they will welcome the chapter written especially for them (Chapter XIII). To many nurses the state laws as they affect them directly, are unfamiliar. They are aware of the

professional and ethical obligations of their practice, but what the law permits them to do, or how the law may place the blame on them for an act they assumed was authorized by a physician, are matters needing a great deal more study than most nurses have given them.

Problems of special interest to public health nurses discussed in this chapter are: standing orders from state and county health departments and in private agencies; parents' refusal to provide care for their sick child; breaking of quarantine; responsibility for reporting communicable disease, medical supervision of the sick, legal status of the medical supervisor, industrial nursing responsibilities, legal aspects of the control of tuberculosis and venereal disease, premarital examinations, prenatal tests, vital statistics, birth certificates, stillbirths and child adoption, protection, placing, and child labor.

As ignorance of the law, especially among those supposedly well educated and trained in a profession, does not excuse a nurse from blame, one lesson that this book drives home is the necessity for knowing the law of the state in which one is practising as it relates to public health and public health nursing.

Administrators of nursing service will find useful information in the chapters on serving as a witness, court testimony, use of confidential records, subpoena, privileged communications, and procedures in cases of criminal action. Altogether a valuable book to have on hand as a reference.

DOROTHY DEMING

A Sanitary Code. Containing Definitions and Interpretations for Guidance of Manufacturers of Paper Packaging Materials and Containers for Perishable Foods—By J. R. Sanborn. Geneva, N. Y.: New York State Agricultural Experiment Station, Cornell

University, 1945. 16 pp. Mimeographed. Free from publisher, address requests to author.

This code is a statement of sanitary objectives for the guidance of the industry, prepared at the request of certain manufacturers. It covers all forms of paper and paperboard products used in packaging or as containers or closures for perishable foods. Among the items included are: Use of clean, sanitary virgin stock; prohibition against poisonous or deleterious materials or adhesives; waterproofing; protection from contamination; bacteriological standards for disintegrated paper stock and for the finished container and closure; sanitary standards for the converting plant; health and cleanliness of personnel. A plant inspection form is presented which incorporates the detailed requirements.

The code is an elaboration of the standards promulgated by the Public Health Service and other health agencies, seasoned with several years' experience by the author in actual work with the plants and in the laboratory. The requirements are being met by manufacturers whose processes are clean and sanitary. Paperboard produced by the larger mills complies 98 per cent of the time with the limit of 250 colonies per gram of disintegrated stock. Compliance by all members of the industry with the provisions of this code through a system of self policing will win the sympathetic support of health authorities. Administrative health officers, milk and food control officials, and public health engineers should be conversant with this effort of the industry.

A. W. FUCHS

The Art of Home Nursing—By Betty Quinn Wagner. Philadelphia: Davis, 1945. 314 pp. Price, \$2.00.

This is a book intended for every individual who may, as the author states, need to know simple nursing technics in

everyday home situations. Unfortunately it attempts to cover a very wide field in a very cursory fashion and is scattered in its focus. The reader is left with many questions unanswered, and one wonders what is to be gained by such suggestions as "compile a scrapbook of your Ideal Dream Home" and "read a copy of the Pure Food, Drug and Cosmetic Act at the Public Library."

The difference in function between a registered professional and a licensed practical nurse is not made clear, nor is there mention of visiting and public health nurses, or how to secure them.

In the field of technics to be carried out by the home nurse, the procedures are confused in order, (for example, page 51, in which the "nurse" is instructed to stop and chart the degrees of temperature before cleaning the rectal thermometer), and are at times too technically described for the average "lay" reader. Not many home nurses will be able to use the "conversion tables" (p. 116) in giving medicines and one might question the "therapeutic dietary rules" for "kidney trouble," gall-bladder trouble and other ailments (pp. 137-138).

The author is at her best when describing a limited field of care in which a few simple directions are stressed, as in care of the aged and chronically ill (Chap. XIV). DOROTHY DEMING

Physicians' Guidebook to Public Health Laboratory Services—Hartford, Conn.: Connecticut State Department of Health, 1945. 128 pp. Free from publisher.

Drs. Stanley H. Osborn, Friend Lee Mickle, and their colleagues of the Bureau of Laboratories of their Department of Health have put us all in their debt and should be congratulated by their fellow professionals in local and state services for the clear, convenient, and comprehensive information they

have set forth for the use of the practitioner of medicine.

Taking advantage of the A.P.H.A. report on *Control of Communicable Diseases* as a background, the authors of this latest contribution to uniformity of fact and resources for administrative purposes, have not only briefed the standard data on etiological agent, source of infection, mode of transmission, and prevalence of each of the 82 disease entities already widely dealt with, but have added ten items, of parasitic infestations and bacterial and other infections, for the identification of which the physician to the sick needs confirmation or correction by laboratory procedures.

The public health laboratory, indispensable alike for the health officer, the epidemiologist, and the family or hospital physician, has in this guidebook done a good job of salesmanship. Taken together with the A.P.H.A. report on *Communicable Disease Control*, now well on toward its third hundred thousand copies, this Connecticut State Department of Health publication of the laboratory diagnostic resources makes it easy to learn and practise modern medicine in at least that field, which, since the time of Pasteur, has brought increasing returns in terms of lives saved and illnesses mitigated.

Every physician wants to know exactly what his nearest public health laboratory offers, how specimens must be presented and, above all, the limitations of the laboratory tests in establishing or altering the clinical diagnoses.

HAVEN EMERSON

Penicillin Therapy, including Tyrothricin and Other Antibiotic Therapy—By John A. Kolmer, M.D. New York: D. Appleton-Century, 1945. 285 pp. Price, \$5.00.

This is an excellent summary of available knowledge on the use of penicillin and other antibiotics in the treatment

of human disease. It contains a very complete bibliography of original publications on the theoretical and practical aspects of these therapeutic agents. New information is accumulating rapidly and it is expected that this volume will soon be outdated. After having made such an excellent beginning, it is assumed that new editions of this book will appear from time to time as the need arises. At the present

time this volume provides for the practising physician easy access to available knowledge.

DAVID G. RUTSTEIN

The Book Service reports that one mail on November 21 brought in 40 individual requests and one request for 100 copies of *The Control of Communicable Diseases*, of which the circulation now approaches 200,000 copies.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

They Just Stop Breathing!—Though this is probably not immediately your business, the matter is so out-of-the-ordinary that you will be curious about it. An equalizing pressure chamber has been developed to induce lung rest for patients with bilateral tuberculosis. When respiration stops the lesions in both sides of the lungs have a chance to heal—and they did so in 6 out of 10 far advanced cases.

BARACH, A. L. The Treatment of Pulmonary Tuberculosis in an Equalizing Pressure Chamber. *Am. Rev. Tuberc.* 52, 2:122 (Aug.), 1945.

Job for DDT?—Continuance of sporadic cases of St. Louis encephalitis since the last epidemic indicates the persistence of an infectious agent. Epidemiologic findings suggest the possibility that blood sucking vectors are involved. Dog ticks, mosquitoes, chicken mites are all suspect. The last word remains to be said.

BIATTNER, R. J., and HEYS, F. M. St. Louis Encephalitis. *J.A.M.A.* 129, 13:854 (Nov. 24), 1945.

When Does Negligence Become Criminal?—There are a half million hospital attendants in these United

States exposed to the occupational hazard of tuberculosis. The percentage of hospitals which now have inadequate tuberculosis control or none is not so disturbing as is the large number that have no post-war plans to create this safeguard.

BRAHDY, L. Control of Occupational Tuberculosis in Hospitals. *J. Indust. Hyg. & Toxicol.*, 27, 8:234 (Oct.), 1945.

Sauer Success Story—In Boston, 3,000 children were immunized against whooping cough with Sauer's vaccine or a detoxified antigen. Of the exposed Sauer-immunized children 9 per cent contracted pertussis; 67 per cent of those "protected" by the detoxified antigen came down with the disease; while 82 per cent of the controls succumbed. It may be added that the other vaccine did modify the course of the disease in a majority of cases.

CRAVITZ, L., and CAULEY, J. H. Pertussis Immunization Program of the Boston Health Department. *J.A.M.A.* 129, 8:539 (Oct. 20), 1945.

Hungry Mosquitoes—Though this study does not indicate that anopheline mosquitoes necessarily fly in dangerous numbers beyond the "one mile limit," it does show that they will fly further,

especially if no succulent humans are nearer to furnish an easy meal.

EYLES, D. E., *et al.* Long-range Dispersal of *Anopheles quadrimaculatus*. Pub. Health Rep. 60, 43:1265 (Oct. 26), 1945.

Sans Teeth, etc.—Three papers on national dental needs read at the last meeting of our own American Public Health Association are mentioned here because you may want to know what the dentists were talking about when your back was turned. Of every hundred Americans only 27 visit the dentist. Yes, there is a whale of a lot to be done—and a minnow of organization to do it.

FULTON, J. T. A National Dental Care Program: Presentation of the Dental Problem (and two related papers). J. Am. Dent. A. 32, 19 (Oct. 1), 1945.

—“We Have Left Undone . . .”—Taxpayers shell out 11 million dollars annually in direct costs for the maintenance of paretics and—don't forget—there are other costly and late manifestations of syphilis. Money loss of income adds an additional charge of 112 million dollars against paresis alone. We will continue to pay through the nose for our earlier sins of omission in venereal disease control.

ISKRAANT, A. P. The Economic Cost of Paresis in the United States. Ven. Dis. Inform. 26, 8:175 (Aug.), 1945.

Next Best to a Satisfactory Diet—This authoritative discussion on the use and abuse of vitamins concludes that self-interest alone should induce commercial concerns to censor their advertising to eliminate false claims. Someone should tell this to the pill-makers who make the night air-waves hideous.

JOLLIFFE, N. The Preventive and Therapeutic Use of Vitamins. J.A.M.A. 129, 9:613 (Oct. 27), 1945.

An Old Friend—For more than twenty years periodic health examinations have been preached, but honest

investigation indicates that they have played only a minor rôle in preventive medicine. If it is looked upon as a screening process to be given at a reasonable cost the health examination might become a more useful tool, opines this writer.

LEAVELL, H. R. Future of the Periodic Health Examination. South. M. J., 38, 8:549 (Aug.), 1945.

Quote—In patients with scarlet fever treated with penicillin . . . streptococci disappear . . . within forty-eight hours, and if treatment is continued for seven days . . . (they) do not reappear. **Unquote.** Though the number of cases is small the conclusion, slightly abbreviated, seems worth spreading before you.

MEADS, M., *et al.* Penicillin Treatment of Scarlet Fever. J.A.M.A. 129, 12:785 (Nov. 17), 1945.

Even the Rats Must Be Hungrier—Vessels from foreign ports are bringing in more rats.

OLESEN, R. Increase of Rat Infestation of Vessels Coming to New York. Pub. Health Rep. 60, 44:1295 (Nov. 2), 1945.

What Next!—Experience reported here indicates that women may be allowed to get out of bed on the first or second day postpartum to eat their meals, go to the toilet, and await bed making. No harmful results occurred and the majority of patients liked the new arrangement.

ROSENBLUM, G., *et al.* Early Rising in the Puerperium. J.A.M.A. 129, 13:849 (Nov. 24), 1945.

Not Bad for a Nation of Cripples!—You'll find a lot of useful statistics about national and industrial health in this paper which tells how a wartime labor force augmented largely by 5 million 4-F's and a lot of women and old men produced 170 billion dollars worth of war material. Our farm popu-

lation, severely drained and in dubious physical shape, increased agricultural production by a third. You'll wonder how they ever managed to do the job.

ROWNTREE, L. G. The Coming Age of Industrial Medicine. J.A.M.A. 129, 9:595 (Oct. 27), 1945.

A Psychiatrist Speaks Up—Our democratic principles have but two objectives—to insure and increase the dignity and security of the individual. These goals are reached through equality of men, rule by the people, civil liberties, and economic security. Without democracy there can be no mental health. Health workers all have an inescapable responsibility: to

do their full share toward making this a democratic nation.

SCHREIBER, J. The Interdependence of Democracy and Mental Health. Ment. Hyg. 29, 4:606 (Oct.), 1945.

Fluorine in Pill-form—Instead of adding fluorine to drinking water, these investigators administered it in pills. To some children they gave it in conjunction with extra vitamins C and D. Their findings are sufficiently worth while for you to make the effort to hunt out the paper. No summary here to please the lazy.

STREAM, L. P., and BEAUDET, J. P. Inhibition of Dental Caries by Ingestion of Fluoride-Vitamin Tablets. New York State J. Med. 45, 20:2183 (Oct. 15), 1945.

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed in future issues.

- THE ADJUSTMENT OF THE NERVOUS VETERAN IN INDUSTRY.** By Meyer Brown, M.D. Chicago: Zurich Insurance Cos., 1945. 52 pp. Price, \$10.
- BIOENERGETICS AND GROWTH.** With Special Reference to the Efficiency Complex in Domestic Animals. By Samuel Brody, Ph.D. New York: Reinhold, 1945. 1023 pp. Price, \$8.50.
- THE CHEMISTRY AND TECHNOLOGY OF FOOD AND FOOD PRODUCTS.** By Morris B. Jacobs, Ph.D. New York: Interscience, 1944. Vol. I—952 pp. Vol. II—890 pp. Price, \$19.00.
- THE CLINICAL APPLICATION OF THE RORSCHACH TEST.** By Ruth Bochner, M.A., and Florence Halpern, M.A. 2d ed. rev. New York: Grune & Stratton, 1945. 331 pp. Price, \$4.00.
- COLLECTED REPRINTS OF THE GRANTEES OF THE NATIONAL FOUNDATION FOR INFANTILE PARALYSIS, 1944, VOL. V.** New York: National Foundation for Infantile Paralysis, 1945. Publication No. 33D.
- THE CONTINUING BATTLE FOR THE CONTROL OF THE MIND OF YOUTH.** By Porter Sargent. Reprinted from the 29th edition of *A HANDBOOK OF PRIVATE SCHOOLS*. Boston: Porter Sargent, 1945. 158 pp. Price, \$1.50.
- DAIRY BACTERIOLOGY AND PUBLIC HEALTH. A Handbook for Veterinarians and Milk Sanitarians.** By C. S. Bryan, D.V.M. Minneapolis: Burgess Publishing Co., 1945. 33 pp. Price, \$1.00.
- EFFECTIVE LIVING.** By C. E. Turner, Dr.P.H., and Elizabeth McHose, M.A. 2d ed. St. Louis: C. V. Mosby, 1945. 432 pp. 164 illus. Price, \$2.00.
- ESSENTIALS OF NEURO-PSYCHIATRY.** A Textbook of Nervous and Mental Disorders. By David M. Olkon, M.D. Philadelphia: Lea & Febiger, 1945. 310 pp., illus. Price, \$4.50.
- FACTS AND FIGURES ABOUT INFANTILE PARALYSIS.** New York: National Foundation for Infantile Paralysis, 1945. 30 pp. Free from publisher, 120 Broadway, New York 5, N. Y.
- FRONTIERS IN CHEMISTRY.** Vol. III—ADVANCES IN NUCLEAR CHEMISTRY AND THEORETICAL ORGANIC CHEMISTRY. Edited by R. E. Burk and Oliver Grummitt. New York: Interscience, 1945. 178 pp. 38 illus. Price, \$3.50.
- THE FUTURE OF THE AMERICAN HOSPITAL SYSTEM.** 1945 Hospital Review. Chicago: American Hospital Assn., 1945. 63 pp. Price, \$25.
- THE GROWTH OF PERSONNEL MANAGEMENT IN GREAT BRITAIN DURING THE WAR, 1939-1944.** By G. R. Moxon. Reprinted from the *International Labour Review*, December, 1944. London: Institute of Labor Management, 1945. 32 pp. Price, \$25.
- HEALTH EDUCATION IN ELEMENTARY AND SECONDARY SCHOOLS.** Prepared by the Kansas State Policy-Making Committee on Health Education. Topeka: Kansas State Board of Health, 1945. 82 pp.
- HEALTH EDUCATION IN COLLEGES.** Prepared by the Kansas State Policy-Making Committee on Health Education. Topeka: Kansas State Board of Health, 1945. 39 pp.
- HEALTH SERVICE AREAS.** Requirements for General Hospitals and Health Centers. By Joseph W. Mountin, Elliott H. Pennell and Vane M. Hoge. Washington, D. C.: Government Printing Office, 1945. *Public Health Bulletin* 292. 68 pp. Price, \$25.
- HYPNOANALYSIS.** By Lewis R. Wolberg, M.D. New York: Grune & Stratton, 1945. 355 pp. Price, \$4.00.

ASSOCIATION NEWS

PUBLIC HEALTH ASSOCIATION OF NEW YORK CITY HOLDS VICTORY MEETING

The Public Health Association of New York City held a two day meeting in New York City on December 13 and 14 in collaboration with the American Public Health Association. Although emphasis was laid especially on developments locally, a good part of the program was devoted to the transitional period between war and peace, and to the broad orientation of public health workers. About 700 persons were in attendance. The meetings were held under the presidency of Sol Pincus, C.E., Deputy Commissioner of Health, New York City Department of Health; Erank Kiernan of New York City was Chairman of the Program Committee and Secretary. The Committee on Arrangements was headed by John L. Rice, M.D., and that on publicity by Horace H. Hughes. Participants from outside New York City included Abel Wolman, Dr.Eng., Baltimore; Ira V. Hiscock, Sc.D., Yale University, New

Haven; George T. Palmer, Dr.P.H., U. S. Public Health Service, Washington; Warren F. Draper, M.D., Deputy Surgeon General, U. S. Public Health Service, Washington; Theodore A. Olson, University of Minnesota, Minneapolis; J. J. Bloomfield, Industrial Hygiene Division of the U. S. Public Health Service, Washington; Robert H. Riley, M.D., State Department of Health, Baltimore; W. Palmer Dearing, M.D., Division of Public Health Methods, U. S. Public Health Service, Washington; C.-E. A. Winslow, Dr.P.H., New Haven; Edward S. Rogers, M.D., Asst. Commissioner for Medical Administration, New York State Department of Health, Albany; Mayhew Derryberry, Ph.D., Chief of Field Activity in Health Education, U. S. Public Health Service, Washington; and Amos Christie, M.D., Department of Pediatrics, Vanderbilt University School of Medicine, Nashville.

GOVERNING COUNCIL ELECTIONS

The A.P.H.A. Governing Council has completed its 1945 election of Fellows, Life Members, and Affiliated Societies. The South Dakota Public Health Association was admitted as an Affiliated Society, 7 Life Members were approved, and the following individuals were elected to Fellowship.

Health Officers Section

George H. Becker, M.D., Director, Bureau of Communicable Diseases, San Francisco Department of Public Health, San Francisco, Calif.
Millard B. Bethel, M.D., M.P.H., Health

Officer, Cabarrus County Health Department, Concord, N. C.

Philip E. Blackerby, M.D., State Health Commissioner, Louisville, Ky.

Leroy E. Burney, M.D., M.P.H., State Health Commissioner, Indianapolis, Ind.

George F. Campana, M.D., M.P.H., State Health Officer, Bismarck, N. D.

F. R. Nicholas Carter, M.D., Health Officer and Secretary, Board of Health, South Bend, Ind.

Albert C. Edwards, M.D., M.P.H., Director, St. Clair County Health Dept., Port Huron, Mich.

Floyd M. Feldman, M.D., Dr.P.H., Health Officer, Rochester City Health Dept., Rochester, Minn.

Henry A. Holle, M.D., Surgeon, U. S. Public Health Service, Washington, D. C. (on UNRRA assignment abroad)

Roscoe P. Kandle, M.D., M.P.H., Director, Division of Local Health Service, State Board of Health, New Orleans, La.

Jacob H. Landes, M.D., M.P.H., Senior Health Officer, Department of Health, New York, N. Y.

Frederick D. Mott, M.D., C.M., Chief Medical Officer, Farm Security Administration, Washington, D. C.

Frederick A. Musacchio, M.D., M.S.P.H., Director, Laredo-Webb County Health Unit, Laredo, Tex.

Emil A. Palmquist, M.D., M.P.H., City Health Commissioner, Seattle, Wash.

Angelo M. Perri, M.D., M.P.H., Chief of Communicable Disease Division, Department of Public Health, Philadelphia, Pa.

William A. Powell, M.D., Contra Costa County Health Officer, Martinez, Calif.

C. L. Putnam, M.D., M.S.P.H., Deputy Commissioner and Director of Local Health Services, State Department of Health, Des Moines, Iowa

Arthur L. Ringle, M.D., C.P.H., Director, State Department of Health, Seattle, Wash.

Mason Romaine, M.D., M.P.H., Health Officer, Petersburg, Va.

Roy M. Seideman, M.D., Dr.P.H., Industrial Hygiene Physician, State Department of Health, Hartford, Conn.

Ellis D. Sox, M.D., C.P.H., Chief, Division of Local Health Service, State Department of Public Health, San Francisco, Calif.

Major General Morrison C. Stayer, M.C., Chief Surgeon, North African-Mediterranean Theater of Operations, U. S. Army (overseas address)

James L. Troupin, M.D., M.S.P.H., District Health Officer, Health Department, New York, N. Y.

I. Oscar Weissman, M.D., M.P.H., Surgeon (R), U. S. Public Health Service; Director, Muskogee City-County Health Dept., Muskogee, Okla.

Maurice S. Whiteside, M.D., Health Officer, Cullman County Health Dept., Cullman, Ala.

John M. Whitney, M.D., Superintendent of Health, New Orleans, La.

Charles L. Wilbar, Jr., M.D., President, Territorial Board of Health, Honolulu, T. H.

Ralph C. Williams, M.D., Assistant Surgeon General and Chief, Bureau of Medical Services, U. S. Public Health Service, Washington, D. C.

and Head, Department of Surgery and Medicine, Michigan State College, East Lansing, Mich.

Irma L. Comstock, B.S., Principal Biologist, State Board of Health Laboratory, Jefferson City, Mo.

William A. Feirer, M.D., Sc.D., Vice-President and Director, Medical Research Division, Sharp & Dohme, Philadelphia, Pa.

Harald N. Johnson, M.D., Member of Staff and Director of Rabies Study, International Health Division, Rockefeller Foundation, Montgomery, Ala.

David B. Lackman, Ph.D., Assistant Bacteriologist, U. S. Public Health Service, Hamilton, Mont. (on military leave)

Einar Leifson, Ph.D., Professor of Bacteriology, University of South Dakota, Vermillion, S. D.

Benjamin S. Levine, Ph.D., Director, Division of Laboratories, State Board of Health, Pierre, S. D.

Robert P. Myers, Ph.D., Chief Bacteriologist, Research Laboratory, National Dairy Products Corp., Baltimore, Md.

Wade W. Oliver, M.D., Professor of Bacteriology, Long Island College of Medicine, Brooklyn, N. Y.

Clarence C. Ruchhoff, B.S. in Ch.E., Principal Chemist, U. S. Public Health Service, Cincinnati, Ohio

Roy Schneider, Ph.D., Bacteriologist in Charge, Bacteriological Section, Industrial Hygiene Research Laboratory, National Institute of Health, Bethesda, Md.

Robert M. Shaw, M.D., D.P.H., Professor of Bacteriology and Hygiene, University of Alberta, Edmonton, Alberta

Lt. Comdr. Frank H. Stubbs, USN, Executive Officer, Duke University N.R.O.T.C., (formerly Director, Branch Laboratory, Georgia State Health Dept.), Albany, Ga.

A. Elizabeth Verder, Ph.D., Bacteriologist, National Institute of Health, Bethesda, Md.

Vital Statistics Section

Marta Fraenkel, M.D., Medical Advisor, Bureau of Research and Statistics, Social Security Board, Washington, D. C.

Marjorie E. Gooch, Sc.D., Chief, Health Statistics Section, Division of Statistical Research, Children's Bureau, Washington, D. C.

Iwao M. Moriyama, Ph.D., C.P.H., Senior Social Science Analyst, Bureau of the Census, Washington, D. C.

Marcelino Pascua-Martinez, M.D., Associate Professor, Johns Hopkins School of Hygiene and Public Health, Baltimore, Md.

Elliott H. Pennell, B.S., Senior Statistician, U. S. Public Health Service, Bethesda, Md.

A. Hardisty Sellers, M.D., D.P.H., Medical

Laboratory Section

Claude S. Bryan, D.V.M., Ph.D., Professor

Officer in charge of Medical Statistics,
Royal Canadian Air Force, Toronto, Ontario

Engineering Section

Col. William A. Hardenbergh, Sn.C., Director,
Sanitary Engineering Division, Surgeon
General's Office, U. S. Army, Washington,
D. C.

Arthur H. Herberger, C.E., M.S., Director,
Division of Sanitation, Nassau County De-
partment of Health, Mineola, N. Y.

Industrial Hygiene Section

August Baier, M.D., Medical Director, Des
Moines Ordnance Plant, U. S. Rubber Co.,
Des Moines, Iowa

Edgar C. Barnes, B.S., Industrial Hygiene
Engineer, Westinghouse Electric Corpora-
tion, East Pittsburgh, Pa.

Rodney R. Beard, M.D., M.P.H., Assistant
Professor of Public Health and Preventive
Medicine, Stanford Medical School, San
Francisco, Calif.

Harold T. Castberg, M.D., Chief, Bureau of
Adult Health, State Department of Public
Health, Berkeley, Calif.

Walter E. Doyle, M.D., Chief, Medical Unit,
Industrial Hygiene Division, U. S. Public
Health Service, Washington, D. C.

John W. Dugger, M.D., Director, Division of
Industrial Hygiene and Factory Inspection,
State Board of Health, Jackson, Miss.

Anna M. Fillmore, R.N., M.P.H., Industrial
Nursing Consultant, Visiting Nurse Service
of New York, New York, N. Y.

Donald O. Hamblin, M.D., Medical Director,
American Cyanamid Co., New York, N. Y.
Clifford Kuh, M.D., Dr.P.H., Director of

NEWS FROM THE FIELD

THE PRESIDENT'S HEALTH MESSAGE

On November 19, President Harry S. Truman presented to a joint session of Congress a comprehensive health message—the first message of any President to deal thus completely with the broad problems of national health and the means for their solution—in fact, it has been said to be the first presidential health message of any kind to Congress. He said in part: “We should resolve now that the health of this nation is a national concern; that financial barriers in the way of attaining health shall be removed; that the health of all the citizens deserves the help of all the nation.”

The President outlined five unmet problems and sketched, in principle, the means for their solution. These are:

1. The distribution of physicians in the United States is grossly uneven and is matched by inequalities in hospitals and other health facilities. About 1,200 counties representing 15,000,000 persons have either no local hospital or none that meets the minimum standards of professional associations; 31 counties, each with more than a thousand inhabitants, in 1940 had not a single practising physician. In the nation as a whole the proportion of physicians to population is as favorable as anywhere in the world. The disparity of their distribution is due to lack of adequate facilities for medical treatment and to the low income levels in many communities which make it difficult and often impossible for doctors to make a living. He suggests that the 60,000 doctors and tens of thousands of other professional personnel now being demobilized from the armed forces cannot be assigned, but must be attracted to communities by adequate facilities for

the practice of medicine and by assurance of economic security.

The President recommends that the federal government provide financial and other assistance for the construction of needed hospitals, health centers, and other medical, health, and rehabilitation facilities. It should be possible to meet deficiencies in hospital and health facilities so that modern services—for both prevention and cure—can be accessible to all the people.

2. There is need for the development of local public health services and maternal and child care. Although some 18,000 local governmental units have responsibility for health service, nevertheless 40,000,000 citizens, a large majority of them in rural areas, live in communities lacking full-time local public health service. At the present rate of progress it would take more than a hundred years to cover the whole nation. We are only beginning to realize our potentialities in achieving physical well-being for all our people.

To develop full-time public health services throughout the nation the President recommends an extension of the present federal-state coöperative relationships whereby states and localities receive financial aid for local services. These services should be financed by states and localities, and federal grants should be in proportion to state and local expenditures and should bear some relation to the financial ability of the states.

3. The third basic problem concerns medical research and professional education. Research can do much to develop ways to reduce those diseases of body and mind which now cause most sickness, disability, and premature

death. And research can do much toward teaching us how to keep well and how to prolong healthy human life. More coördinated research is needed on the cause, prevention, and cure of cancer, for example, which currently causes 160,000 deaths a year. There is also special need for research on mental diseases and abnormalities. Mentally ill are estimated to number two million; they occupy half of the existing hospital beds, at a cost of about \$500,000,000 a year; 125,000 new mental cases are admitted to institutions annually. He says further that the money invested in research pays enormous dividends. If anyone doubts this, let him think of penicillin, plasma, DDT, and new rehabilitation techniques.

Professional education and medical research should be strengthened where necessary through federal grants-in-aid to public and to non-profit private agencies and institutions.

4. The high cost of individual medical care is the principal reason why people do not receive the medical care when they need it. This is true not only of needy persons but for a large proportion of normally self supporting persons as well. At present part of this deficiency is being met, particularly in rural areas, by the kindness or private charity of the individual physician, who should not be expected to carry so heavy a load. The President estimated that on the average 4 per cent of the national income is absorbed for medical care. He suggests therefore distributing the costs through expansion of the compulsory insurance system, operating on the well developed insurance principle of spreading the risk of any unforeseeable personal or family calamity—fire, burglary, sickness.

As to the organization and administration of such a system, the President says medical services are personal. Therefore, the nation-wide system must

be highly decentralized in administration. The local administrative unit must be the keystone of the system so as to provide for local services and adaptation to local needs and conditions. Locally as well as nationally, policy and administration should be guided by advisory committees in which the public and the medical professions are represented.

He further stresses the continued personal relationship between patient and doctor under such a system, the enlargement of free choice of physicians by the removal of financial barriers, and the free choice by physicians to practise within or without the system.

5. The fifth problem has to do with loss of earnings due to illness. On an average day about 7,000,000 persons are so disabled by sickness or injury that they cannot go about their usual tasks. Of these, about 3,250,000 are persons who would otherwise be working or seeking employment. Every year four or five hundred million working days are lost from productive employment because of illness and accident—about forty times the number of days lost because of strikes, on the average, during the ten years before the war.

A comprehensive health program must include the payment of benefits to replace at least part of the earnings that are lost during the period of sickness and long-term disability. This protection, according to the President, can be readily and conveniently provided through expansion of the present social insurance system, with appropriate adjustment of premiums.

From the newspaper comment we quote from the *New York Times* editorial of November 21:

"The President's message on a five-point health program deals thoroughly with the medical implications of the Social Security Act. Evidently to offset opposition, fully a third of the message argues persuasively for the better distribution of medical care and

the reduction of its cost and dwells on the inappropriateness of the term 'socialized medicine' when beneficiaries of medical insurance pay their own premiums and choose their own doctors in accordance with tradition. We have, then, both a message to Congress and an educational document which should blow away much of the fog of controversy.

"The plans outlined by the President are ambitious and far-reaching. Nowhere in the world is there anything quite like his proposed integration of hospitals and medical centers built and operated at public expense with health service, physicians, maternal and child care, dentistry, medical education and research."

The *New York Herald Tribune* of November 21 says editorially in part:

"President Truman's message on national health was, in the first place, a comprehensive and impressive survey of the strength and weakness of medical care in the United States. Few would attempt to dispute the reality of the problems he set forth or the challenge they present to a powerful and wealthy nation. Moreover, the President showed an obvious concern lest a national health program become too unwieldy, over-centralized, bureaucratic. He emphasized continually the need for local administration, for the utmost in voluntary coöperation, for as much flexibility as possible. The President's message deserves the most careful study because of the magnitude of the problem with which he seeks to deal and the thoughtful attention he has given it."

DR. CUMMING COMPLETES 25 YEARS WITH PAN AMERICAN SANITARY BUREAU

On December 20, 1945, Dr. Hugh S. Cumming, Surgeon General (Retired), U. S. Public Health Service, completed twenty-five years as Director of the Pan American Sanitary Bureau, the official health organization of the American Republics and the oldest international health body in the world. When Dr. Cumming retired from the Public Health Service in January, 1936, he did not give up his interest in public health, but decided to devote himself to improving inter-American health conditions and good will through

his continued, full-time direction of the Pan American Sanitary Bureau. In 1920 when Dr. Cumming first assumed direction of this Bureau, available funds permitted the employment of only one clerk to collect and distribute epidemiological information. Since those early days, however, the Bureau has grown, with increased appropriations making possible an increasing participation in inter-American health work. Impetus was given to its growth by the adoption in Habana in 1924 of the Pan American Sanitary Code, "the first and only treaty to be ratified by all the American Republics." For a number of years the Bureau has been sending representatives, including physicians, sanitary engineers, laboratory workers, entomologists, nurses, etc., to Latin America to give advice and assistance to the different republics in their health problems, and undertaking specific campaigns against such conditions as plague, onchocerciasis, venereal diseases, typhus and malaria, organizing nursing schools and hospitals, granting fellowships, and similar coöperative programs. A recommendation was made at the Inter-American Conference held at Chapultepec in February and March, 1945, that the Pan American Sanitary Bureau be given such financial aid and technical and other personnel as may be needed to promote its work of coördination and technical direction of sanitary activities of the Americas.

Dr. Cumming has been honored many times by the American Republics which have granted him the following decorations: Order of Carlos Finlay, Cuba, 1931, Order of El Mérito, Ecuador, 1931, Order of El Sol del Perú, 1934, Order of Honneur et Mérite, Haiti, 1939, Order of Boyacá, Colombia, 1939, Order of Al Mérito, Chile, 1940, Order of Mérito, Juan Pablo Duarte, Dominican Republic, 1943, Order of Eduardo Licéaga, México, 1943, Order of Mérito, Paraguay, 1945. Dr. Cum-

ming was President of the American Public Health Association in 1931.

Dr. Cumming's anniversary has been made the subject of recognition in messages from the highest authorities of the American Republics and the United States. A gold medal has recently been awarded him by the Government of Guatemala to commemorate the anniversary.

NEW ORLEANS ADOPTS TYPHUS CONTROL ORDINANCE

John M. Whitney, M.D., Superintendent of Public Health of New Orleans, La., has reported that the Commission Council of the City of New Orleans has adopted an ordinance aiding the rat control program. An appropriation of \$10,000 has been made for this purpose. E. B. McCrary of the Division of Pest Control of the Health Department is in charge. Copies of the ordinance may be obtained by addressing Dr. Whitney.

NUTRITION FOUNDATION EXTENDS RESEARCH GRANTS

Charles Glen King, Ph.D., Scientific Director of the Nutrition Foundation, Inc., New York City, has announced that the Board of Trustees at the Foundation's annual meeting in November awarded new grants of \$120,565, bringing the total since the establishment of the Foundation to \$1,041,755. Dr. James Bryant Conant, President of Harvard University, was the speaker at the annual luncheon.

Among the institutions receiving grants were Stanford University, Yale University, University of Wisconsin, University of Toronto, Tulane University, University of California, Pennsylvania State College, Cornell University, Duke University, Northwestern University, Meharry Medical College, Harvard University, University of Southern California, and Washington University.

AWARDS OF TYPHUS COMMISSION MEDAL

The Office of the Surgeon General, U. S. Army, Washington, has announced that the United States of America Typhus Commission Medal has been awarded to a group of officers including Lt. Colonel Wilson C. Williams, M.C., formerly State Health Officer of Tennessee, Nashville, and Captain Bernard D. Daitz, Sn.C., of New York City.

TROPICAL DISEASE QUARANTINE

A joint Army-Navy and Public Health Service military quarantine program will take all possible precautions against the introduction of new tropical diseases into this country through the deployment of troops, according to Lt. Col. O. R. McCoy, MC, Director of the Tropical Disease Control Division, Office of The Surgeon General, who spoke at the recent meeting of the Southern Medical Association in Cincinnati.

This precautionary program, Colonel McCoy pointed out, is carried on in addition to the preventive measures taken by the services for all troops serving overseas. Immunization and high standards of sanitation have been enforced, and the Army has taken definite steps to minimize secondary cases of malaria among soldiers already returned to the United States. The latter precaution requires that soldiers taking suppressive medication against malaria when they return to this country continue to take the drug for twenty-eight days.

Dengue, sandfly fever, and scrub typhus are limited in their course, having no recurrences, and so offer little hazard as diseases imported by returned soldiers. It has also been found that the incidence of carriers of bacillary dysentery is "extremely low" in military personnel, and that the chances of transmission of filariasis in the United States is very slight.

"Troops are examined," Colonel

McCoy concluded, "before departure from abroad and after arrival in this country to identify and screen out for treatment individuals who may have acquired communicable diseases during overseas service. Also new regulations have been formulated which are intended to prevent the introduction of disease through infected animals, plants or insects."

NEW AMERICAN STANDARD BUILDING CODE

A new American Standard giving designers data on the loads a building can carry with safety has just been approved by the American Standards Association. This marks another advance in the development of a complete series of standards in the building field and will help to answer such questions as: how strong should floors and walls be made in factories, office buildings, and theaters to prevent them from collapsing when occupied by the machinery, desks, or audiences which they accommodate? And whether it is necessary in any particular part of the country to provide especially strong construction to resist wind pressures, to withstand earthquake shocks, and to prevent collapse of roofs under the load of winter snow.

MICHIGAN PUBLIC HEALTH ASSOCIATION

The Michigan Public Health Association held its 25th Annual Public Health Conference in Grand Rapids November 7 to 9. The theme of the three day conference was "Reconversion," and the attendance was 610.

The following new officers were elected:

President—David Littlejohn, M.D., Dearborn
President-elect—K. R. Gibson, D.D.S., Detroit
Vice-President—H. J. Dunsmore, Battle Creek
Secretary-Treasurer—Marjorie Delavan, Lansing
Representative on A.P.H.A. Governing Council—Nathan Sinai, Dr.P.H., Ann Arbor

RESEARCH FUND FOR HEART DISEASE

A joint committee of the American Life Convention and the Life Insurance Association of America has announced the creation of a \$3,500,000 medical research fund which is being made available through the participation of 143 life insurance companies in the United States and Canada. M. Albert Linton, chairman of the joint committee, states that the first research will be planned in diseases of the heart and arteries because of the primary importance of these diseases to the public and to life insurance policy holders. He compared the deaths from heart disease during the 3½ years of war in the United States with those from combat deaths in all branches of the armed services with 1,400,000 of the former and 272,000 of the latter.

The allocation of the funds will be made by an advisory council of eight distinguished physicians and it is expected that a recognized leader in the field of medical research will be named to the post of scientific director. Annual contributions of more than \$500,000 each year are expected to raise the total sum in six years' time.

GENERAL SIMMONS RECEIVES DISTINGUISHED SERVICE MEDAL

On November 19, 1945, Major General Norman T. Kirk, The Surgeon General of the Army, presented the Distinguished Service Medal to Brigadier General James Stevens Simmons, USA, Chief, Preventive Medicine Service, Office of The Surgeon General, Washington, D. C. The citation which accompanied the medal read as follows:

"Brigadier General James Stevens Simmons rendered exceptionally meritorious service in a duty of heavy responsibility as Chief of the Preventive Medicine Service, Office of The Surgeon General, from November, 1939, to August, 1945. The service he organized and developed carried out a world-wide program of military and civil public health which secured both immediate and enduring bene-

fits by reducing hazards to the health of troops, civilians engaged in essential war work, and refugees and displaced persons. By applying the best available knowledge and fostering research, he developed and extended new information on the causes and prevention of communicable diseases, on the improvement of nutrition for soldiers and on the reduction or elimination of the health hazards of mechanized warfare and adherence to ideals, inspired and established a positive concept of health for troops and civilians. With extraordinary foresight, he was in advance of events, devising measures for health protection before critical needs arose; and with dynamic energy, he overcame severe difficulties. By protecting the health of the Army and conserving the health of the nation, General Simmons contributed directly to winning the war."

MASSACHUSETTS HEALTH OFFICERS ORGANIZE

The health officers of the North Metropolitan State Health District in Massachusetts have organized the North Metropolitan District Health Officers' and Agents' Conference intended to afford members an opportunity to discuss inter-community health problems and to exchange ideas regarding administrative practices.

Officers of the association include Francis P. Denny, M.D., Health Officer, Brookline, President; John D. Crowley, Agent, Cambridge, Vice-President; May C. Welsh, Agent, Malden, Secretary; and A. Daniel Rubenstein, M.D., District Health Officer, Consultant.

KOREAN PHYSICIANS STUDY PUBLIC HEALTH IN THE UNITED STATES

A group of nine physicians from Korea have begun a year of study in the field of public health under the auspices of the International Health Division of the Rockefeller Foundation, according to an announcement by the Office of the Surgeon General, U. S. Army. Three of the physicians are at the Johns Hopkins School of Hygiene, three at the Harvard School of Public Health, and

three at the University of Michigan School of Public Health. According to Major General Norman T. Kirk, the purpose of this year of training is to lay the foundation for a self-sufficient medical service for the Korean nation. For more than thirty years, according to Dr. Kirk, the Japanese have dominated all medical and other scientific work in Korea as well as its national and local government affairs. No Korean has been allowed to serve in a position of responsibility in the nation or in his own community.

PROFESSOR C.-E. A. WINSLOW RECEIVES 1945 ELIZABETH SEVERANCE PRENTISS AWARD

Presentation of the second annual Elizabeth Severance Prentiss National Award in Health Education to Professor C.-E. A. Winslow was made at the luncheon of the fifth anniversary meeting of the Cleveland Health Museum on November 27, 1945. The redesigned award in the form of a plaque is shown. The presentation was made by radio over the N.B.C. network by Dr. James Rowland Angell, President Emeritus of Yale University, in whose medical school Professor Winslow has taught public health for thirty years.

Professor Winslow addressed the

Elizabeth Severance Prentiss Award

more than 600 guests at the luncheon on "Ten Unattained Goals of Public Health," among which he listed organized community health education.

The award was made possible through a grant of Mrs. Elizabeth Severance Prentiss. Its first recipients in 1944 were Mary Swain Routzahn and Edward G. Routzahn (posthumously), to whom Professor Winslow gave credit for the real accomplishments in the field of health education.

PUBLIC HEALTH LABORATORY DIRECTORS' MEETING, CINCINNATI

On November 10 and 11, immediately preceding the meeting of the Southern Medical Association and Associated Societies in Cincinnati, a meeting of the Conference of State and Provincial Public Health Laboratory Directors was held in that city. About half of the state laboratories, the U. S. Public Health Service, and the Department of Pensions and National Health of Canada were represented.

Many current problems of laboratories were outlined in reports of standing committees and discussions of them; and plans were made to increase the activities of the organization in the post-war period. A proposal was entertained to broaden its scope by giving greater participation to personnel of municipal, county, and other public health laboratories and a committee was appointed to draft proposed revisions of the constitution to embody these suggestions.

SOCIAL HYGIENE DAY

The observance of Social Hygiene Day, February 6, 1946, has special significance this year, as the impetus given the whole program of venereal disease control under wartime conditions must be maintained and the goal "the virtual eradication of syphilis and gonorrhea within the foreseeable future" realized.

The American Social Hygiene Asso-

ciation has prepared publicity materials to assist any community group in observing the occasion through meetings, radio programs, or other group activities. The folder *Beyond Victory* is free in quantity and without charge. It describes ways in which Social Hygiene Day can be made effective in your community. Order from the American Social Hygiene Association, 1790 Broadway, New York 19, N. Y.

A NUTRITION PROGRAM WITH THREE-WAY BENEFITS

An unusual experimental program in nutrition was recently started at Flora Stone Mather College, Western Reserve University.

Thirty-six students with a variety of difficulties—organic, physical, and neurological—are under the supervision of seven public health nurses, students in graduate courses in public health nutrition at the University. Each student has had a nutrition program prescribed to fit her individual needs, under the direction of the Professor of Physical Education, the Professor of Home Economics, and the Director of Student Health Service. The public health nurses—each from a different state department of health and one from Puerto Rico—will keep careful records of progress of the students, write a report of the program, and carry it back to their home state. Thus, this program benefits the underpar student, the graduate student in public health nutrition, and eventually, the state health department's service to the public.

INDIANAPOLIS HEALTH CENTER UNDER CONSTRUCTION

Under the direction of the Indianapolis Board of Health, the construction of a health center building as an adjunct to Flanner House was begun on June 13. The building will cost approximately \$105,000. With an additional \$20,000 to be spent for equip-

ment, and will contain clinic, examination and x-ray rooms, and offices for staff members. The work will be tied up with the city's slum clearance project, and, a case finding program of tuberculosis, venereal disease, antepartum medicine, infant and child health, dental and general medicine will be conducted.

CONGRESS ON MEDICAL EDUCATION AND LICENSURE

The Congress on Medical Education and Licensure of the American Medical Association will hold its 42nd annual meeting at the Palmer House, Chicago, on February 11 and 12.

UNRRA REPORTS EUROPE'S EPIDEMICS HELD IN CHECK

No communicable disease "is sufficiently prevalent as to constitute a menace to international health." This word comes from a November 26 report from the Chief of the Epidemic Control Branch of UNRRA's Health Division, Dr. G. Stuart, but with the added caution that the "hump of the difficult winter months has not yet been passed."

A summary of the status of some of the more common communicable diseases follows:

Smallpox—Prevalent only in Italy

Louse-Borne Typhus—D.D.T. has practically eliminated it from British and American zones. Serious in many parts of the Balkans and less serious in Bulgaria and Greece. Can be held in check with D.D.T.

Plague—Only in Malta, but remains a threat because North Africa and Palestine remain infected.

Diphtheria—Incidence high, especially in Germany.

Typhoid Fever—Greatly increased in many countries; in Germany in September it was 30 times the normal rate.

Tuberculosis—Greatly increased in many continental countries.

Syphilis—Progress made in venereal disease control in 20 years virtually wiped out by war years. Syphilis increased three- to nine-fold in most countries, twenty-fold in Germany.

Malaria—Epidemic in Greece; leading cause of illness in Mediterranean basin. Spraying marshland areas with D.D.T. from specially equipped planes is expected to cut the risks of malaria or eliminate it entirely in Greece within a year.

SOUTHERN BRANCH, A.P.H.A., ELECTS OFFICERS

The Southern Branch, American Public Health Association, met during the meeting of the Southern Medical Association in Cincinnati, Ohio, November 14 and 15, under the presidency of R. H. Hutcheson, M.D., Commissioner of Health of the Tennessee State Department of Health, Nashville.

The officers for the ensuing year include the following:

President—Dr. W. K. Sharp; USPHS, Richmond, Va.

First Vice-President—Dr. George H. Denison, Birmingham and Jefferson County Health Officer, Birmingham, Ala.

Second Vice-President—J. M. Jarrett, Director Public Health Engineering Raleigh, N. C.

Third Vice-President—Abbie Weaver, R.N., Director Public Health Nursing, State Board of Health, Atlanta, Ga.

Secretary-Treasurer—Dr. John W. Williams, Jr., State Director of Local Health, State Board of Health, Jefferson City, Mo.

COLUMBIA WILL ADMIT MID-YEAR CLASS

In response to requests, mainly from those recently discharged from the armed services, the School of Public Health of Columbia University, New York, has announced that properly qualified applicants for the Master of Public Health course will be admitted on February 4, 1946. Graduate students so admitted will be expected to spend the summer months in obtaining field experience, returning for two additional quarters of academic work late in September, according to the announcement.

GREEK NATIONAL TUBERCULOSIS ASSOCIATION

The Greek National Tuberculosis As-

sociation, formed in May, 1945, is now in active operation with the Regent of Greece as Patron, according to a report received from J. B. McDougall, Head of the Tuberculosis Section, Health Division, UNRRA Greece Mission, and published in the UNRRA Epidemiological *Bulletin* No. 20.

The Greek Tuberculosis Association will be the first of any in the liberated countries of Europe to become affiliated with the International Union against Tuberculosis, which in pre-war years had its headquarters in Paris. The Greek Association will encourage local medical men to do research on tuberculosis problems peculiar to Greece, such as the incidence of tuberculosis and its clinical behavior in malaria-stricken areas.

RED CROSS NAMES HEALTH SERVICES ADVISORY BOARD

Basil O'Connor recently announced appointment of an Advisory Board on Health Services to coördinate activities of the American Red Cross in the health field. Mr. O'Connor, national Red Cross Chairman, named as board chairman Lewis H. Weed, M.D., of Baltimore. Dr. Weed also is chairman of the medical sciences division of the National Research Council; and director, School of Medicine, Johns Hopkins University.

The committee consists of 109 men and women from 25 states and the District of Columbia, representing every specialty in the field of health. Not only physicians were appointed, but also nurses, dentists, health educators, medical and psychiatric social workers, hospital administrators, medical publicists, nutritionists, pediatricians, public health administrators, and sanitary engineers.

Three members of the advisory board will serve as general vice chairmen. They are: Roger I. Lee, M.D., Boston, Mass., John D. Lyttle, M.D., Los

Angeles, Calif., and John Romano, M.D., Cincinnati, Ohio.

REPRINTS FOR THE DEVASTATED MEDICAL LIBRARIES OF MANILA

In connection with its campaign to help rebuild the medical libraries of Manila which were destroyed during the Japanese occupation, the Academy-International of Medicine requests that medical authors contribute eight or ten reprints of each of their articles which have been published since 1941. They may be sent at the regular parcel post rate of sixteen cents for the first pound and eleven cents for each additional pound, care of A. B. M. Sison, M.D., Philippine General Hospital, Manila, P. I.

HEALTH EDUCATION INSTITUTE IN MASSACHUSETTS

The Massachusetts Tuberculosis League, in coöperation with Simmons College, announces an 8 week health education institute February 4 through March 29, designed primarily "to train assistants in health education to work under supervision in the tuberculosis associations of the state." The course is open also to any education workers in the tuberculosis field and to health workers in voluntary and official agencies of Massachusetts.

The first 5 weeks, at Simmons College, will be devoted to lectures and discussions, the remaining 3 weeks to supervised field work. Address inquiries to Massachusetts Tuberculosis League, 1148 Little Building, Boston 16, Mass.

AMERICAN ASSOCIATION OF PUBLIC HEALTH DENTISTS

Frank C. Cady, D.D.S., Senior Dental Surgeon of the U. S. Public Health Service is now President of the American Association of Public Health Dentists, succeeding Dr. William R. Davis of Michigan.

Dr. Cady was one of the founders of the association, is a charter member and was its first Secretary, a position he filled for five consecutive years.

Other officers elected were: Edward Taylor of Texas, President-elect; C. Ray Taylor of Michigan, Secretary; Linwood G. Grace of Pennsylvania, Treasurer, and Vern D. Irwin of Minnesota, Editor.

\$2,000,000 NURSES' NATIONAL MEMORIAL

Plans for a National Memorial in the District of Columbia to the heroic nurses of World War II in the form of a social center and temporary residence have been inaugurated by a distinguished group of sponsors including top-ranking officers of the Armed Forces and their wives.

PERSONALS

Central States

RUTH E. CHURCH, M.D., M.S.,* who has been Medical Director of the District Health Unit No. 7 at Washington, Iowa, for several years, has resigned to become director of the McDonough-Fulton Bi-County Health Department with headquarters in Macomb and Canton, Ill., effective December 1.

NABOTH O. PEARCE, M.D., of Minneapolis, Minn., has been appointed Tuberculosis Control Officer in the Minnesota Department of Health to direct a state-wide tuberculosis program. The work, which will be financed by a federal grant of \$100,000, will be supplemental to activities now carried on by Dr. Walter J. Marckley, Minneapolis, in the Division of Preventable Diseases, by the local health departments, and the Christ-

mas Seal organizations. The objective of the program is to discover incipient cases of tuberculosis.

Eastern States

MAJOR CARL R. FELLERS,* Head, Food Technology Department at Massachusetts State College, Amherst, has returned to the United States. For 3½ years his headquarters were located at Sydney, Australia. He organized and operated three Army Subsistence Laboratories at Sydney, Melbourne, and Brisbane, and was in charge of all Army Subsistence Inspection (except animal products) in the Southwest Pacific Area.

JOHN THOMAS FULTON, D.D.S.,† has been appointed to the newly created position of Dental Services Adviser in the Division of Research and Child Development of the Children's Bureau, Department of Labor. Dr. Fulton is the technical adviser to the Bureau in the field of services to children and will devote himself primarily to research, administration, and practice in public health dentistry for children. His appointment is indicative of the continued expansion and recognition in the Bureau of the importance of dental health. Dr. Fulton was formerly Chief of the Division of Dental Hygiene of the Connecticut State Health Dept.

COMDR. LEONARD J. GOLDWATER (MC), USNR,* has been released to inactive duty after 4½ years of active service with the Navy. During his time in the Navy, Dr. Goldwater served as Industrial Health Officer at several major naval stations including the Navy Yards at Brooklyn, N. Y., and Pearl Harbor. Dr. Goldwater will resume his position as Assistant Professor of Preventive Medicine at New York University College of Medicine.

H. F. KILANDER, PH.D.,† has joined

* Fellow A.P.H.A.

† Member A.P.H.A.

the staff of the National Tuberculosis Association, New York, as Associate in Health Education. He formerly was Administrative Dean at Panzer College of Physical Education and Hygiene, East Orange, N. J. During the war, he served as Regional Chief in the Industrial Nutrition Program, first in the Federal Security Agency and later in the War Food Administration.

JOHN L. LAVAN, M.D., DR.P.H.,* has resigned as Director of Research for the National Foundation for Infantile Paralysis, New York, to join the staff of the American College of Surgeons, with headquarters for the present at 210 East 68th Street, New York, N. Y.

JAMES LIEBERMAN, D.V.M.,† of Flushing, N. Y., has recently been stationed at the Naval Medical Research Institute, National Naval Medical Center, Bethesda, Md.

ELEANOR BROWN MERRILL † of New York City, Executive Director of the National Society for the Prevention of Blindness, left in November for Montevideo, Uruguay, to attend the Pan American Congress on Ophthalmology.

RALPH S. MUCKENFUSS, M.D.,* who commanded the first Medical General Laboratory in the European theater of operations and the European theater blood bank, has returned from military service to resume his position as Director of the Bureau of Laboratories of the New York City Department of Health. Dr. Muckenfuss had been on military leave since July 22, 1942.

EDWARD W. PALMER † has resigned from his position as Junior Master of Brighton High School, Brighton, Mass., to become Executive Secretary of the Nassau County Cancer Committee effective September 15.

WILLIAM M. SCHMIDT, M.D.,* New York, N. Y., former Medical Direc-

tor for the New York region of the Children's Bureau, U. S. Department of Labor, is en route to Europe to supervise the health and medical services on the continent of the Joint Distribution Committee, major American agency for the relief and rehabilitation of distressed Jews overseas.

Southern States

JOEL C. BEALL,† who has served for some years as public health engineer with Memphis and Shelby County Health Department, Memphis, Tenn., has been called to active duty as Assistant Sanitary Engineer (R) in the Division of Preventable Diseases, Typhus Control Service of the USPHS, with offices in Macon, Ga.

GEORGE B. DARLING, DR.P.H.,* formerly President of the W. K. Kellogg Foundation, who since 1943 has been associated with the Division of Medical Sciences of the National Research Council, Washington, D. C., first as Executive Officer of the Committee on Military Medicine, and later as Vice Chairman of the division, has been appointed Executive Secretary of the National Academy of Sciences and of the National Research Council.

CHANGES IN HEALTH OFFICERS IN FLORIDA:

SIDNEY J. WILLIAMS, M.D., M.P.H.,† formerly Director of the Pike County, Miss., Health Department, has accepted Directorship of the Southeastern Florida Health District with headquarters at Vero Beach.

FRANK L. QUILLMAN, M.D.,† has been appointed Director of the Seminole County Health Unit with headquarters at Sanford. Dr. Quillman was formerly a local health officer and lately has been Director of Venereal Disease Con-

* Fellow A.P.H.A.

† Member A.P.H.A.

trol in the Dade County Health Department.

E. F. HOFFMAN, M.D., M.S.P.H.,† recently resigned as Epidemiologist with the State Board of Health and has accepted the position of Director of the Central Florida Health District with headquarters as Ocala. Dr. Hoffman will also direct the Northern Florida and the Southwestern Florida Health Districts, until officers have been secured for these districts.

M. ESTELLE INGOLDSBY, R.N.,† of the West Virginia State Department of Health, Charleston, has been elected Chairman of the West Virginia State Nutrition Committee.

CHANGES IN HEALTH OFFICERS IN KENTUCKY:

CHARLES D. CAWOOD, M.D.,* who for some years has been Health Officer of the Lexington-Fayette County Board of Health of Kentucky, has resigned as of November 30 to enter private practice.

DR. RALPH GREGG, Sr. Surgeon, U. S. Public Health Service, has been appointed Health Officer of the City of Lexington-Fayette Co. Health Department effective December 1, succeeding CHARLES D. CAWOOD, M.D.,* resigned.

COLONEL JOHN B. YOUMANS, M.C., A.U.S., Assistant Director of the Civil Public Health and Nutrition Division, Office of the Surgeon General, Washington, has recently returned from a 3 months' stay in Europe as chief nutrition consultant.

Western States

HYRUM L. MARSHALL, M.D.,† Professor and Head of the Department of Public Health and Preventive Medicine, has been named Acting Dean of the University of Utah School of Medicine, Salt Lake City.

* Fellow A.P.H.A.

† Member A.P.H.A.

CHANGES IN HEALTH OFFICERS IN OREGON:

ROBERT W. RIPLEY, M.D.,† has resigned as Health Officer of Corvallis to accept a position in the Connecticut State Department of Health.

WILLIAM T. EDMUNDSON, M.D., Newberg, has been appointed Health Officer for Hood River County to succeed DR. CECIL W. MCCAIN, of Hood River, resigned.

EDWARD L. VAN AELSTYN, M.D.,† of Price, Utah, has been appointed Director of the Cowlitz and Wahkiakum Counties Health Departments in Washington State, succeeding DR. THOMAS H. BIGGS, who resigned recently to devote his time to private practice.

Foreign

SIR JOHN BOYD ORR,* of Bucksburn, Aberdeenshire, Scotland, a member of the British Parliament, has been elected Director General of the Food and Agriculture Organization which will have temporary offices in Washington, D. C.

COL. GEORGE M. POWELL, M.C., is the new Assistant Chief Health Officer of the Panama Canal, succeeding COL. ALBERT R. DREISBACH, M.C., whose reassignment in June terminated a seven month tour of duty on the Isthmus.

The Rh Factor, Vitamin K and Rubella Virus in Relation to Infant Mortality and Morbidity*

EDITH L. POTTER, M.D., PH.D.

Department of Obstetrics and Gynecology, The University of Chicago and the Chicago Lying-in Hospital, Chicago, Ill.

WITHIN the last few years several discoveries have contributed to the better understanding of conditions affecting the fetus and newly-born infant. Among the most important of these have been: (1) the discovery of the Rh factor and its relation to erythroblastosis fetalis, (2) the discovery of vitamin K and its relation to hemorrhagic disease of the new-born, (3) the recognition of the harmful effect on the embryo of a rubella infection during the early months of pregnancy.

Until very recently, the etiologic agents responsible for erythroblastosis, hemorrhagic disease, and malformations have been unsuspected in spite of the fact that these conditions have long been recognized clinically. Now the first two groups and part of the last can be added to the pathologic states of the fetus for which causes are known.

ERYTHROBLASTOSIS FETALIS
Erythroblastosis fetalis has been

recognized for many years as a disease characterized by excessive destruction and abnormal production of red blood cells.

It has recently been suggested that the name be changed to hemolytic disease of the new-born, inasmuch as hemolysis is the underlying disturbance responsible for the symptom complex. This name has several advantages, and its use may be advisable, since at times the term erythroblastosis has been applied to any disturbance, regardless of etiology, in which there is unusual erythropoietic activity. The principal drawback is the similarity to "hemolytic anemia" which is used to designate an anemia characterized by increased fragility of erythrocytes. The name erythroblastosis will be retained in this paper.

The excessive hemolysis and the resulting abnormal erythropoiesis are manifested in the living infant by anemia, jaundice, and the presence of immature red blood cells in the circulation. At necropsy they are shown by foci of erythropoiesis in abnormal loca-

* Special Review Article prepared at the request of the Editorial Board.

tions throughout the body, and by deposits of blood pigment in the liver, spleen, and kidneys.

Although all of these manifestations are ordinarily present in infants suffering from erythroblastosis, the various clinical varieties of the disease are dependent upon the relative severity of individual symptoms. The most severe form is commonly known as the hydropic type, since marked generalized anasarca and pleural and peritoneal effusions are the outstanding feature. The anemia is usually more profound than in any other form; erythroblastemia and abnormal erythropoiesis are more excessive. Hydropic infants are frequently stillborn, and if born alive rarely survive more than a few hours.

The icteric form, commonly known as icterus gravis, shows much variation in severity. These infants frequently have an intense and startling jaundice. Although rarely present except in a very mild degree at the time of birth, it subsequently becomes rapidly progressive and assumes a most characteristic hue at 36 to 48 hours. Erythroblastemia is usually present at birth and anemia is ordinarily demonstrable then, or within a short time. The general prognosis is dependent upon the rapidity with which anemia and jaundice appear and the extent to which they progress. The present outlook for some of these infants is hopeless, regardless of treatment; some will survive if given correctly timed transfusions of proper blood in adequate amounts, and some will survive without treatment.

The type in which the anemia is the most prominent symptom and in which jaundice and erythroblastemia are mild or absent has been frequently known as idiopathic anemia of the new-born. These infants make up relatively few of those who have heretofore been included under the diagnosis of erythroblastosis and it is probable that this form of the disease commonly escapes

recognition. It is the most benign form, and although an occasional infant may require a transfusion, the majority will respond to iron and liver therapy and few will die even without treatment.

Until 1941 when Levine and his coworkers¹ recognized the importance of the Rh factor in relation to erythroblastosis, nothing was known of the cause of this condition and there was difference of opinion as to whether the abnormal regeneration or the degeneration of blood cells was the primary disturbance. It has now been definitely established that the disease is a hemolytic anemia generally due to maternal immunization to the Rh factor.

In 1940 Landsteiner and Wiener² reported that rabbits injected with the blood of rhesus monkeys developed agglutinins which reacted not only with rhesus blood but with the bloods of approximately 85 per cent of human beings as well. The human cells which were clumped by the rabbit serum were considered Rh positive (Rh+) and those not clumped, Rh negative (Rh-). The antibodies causing the clumping were known as anti-Rh agglutinins.

Levine and Stetson (1939)³ had previously reported an unusual agglutinin in the blood of a woman giving birth to an infant with erythroblastosis, and in subsequent investigations the similarity of the anti-Rh agglutinin produced in rabbits to an agglutinin frequently found in the blood of women bearing infants with erythroblastosis was established. Wiener and Levine, each with his coworkers, and numerous other investigators have, since that time, corroborated the original observations and added much additional information.

All individuals are born Rh+ or Rh- and remain the same throughout life. The Rh character is inherited in a simple Mendelian manner, with the positive gene dominant over the nega-

tive. It is consequently possible for two Rh+ individuals to have an Rh— child, but impossible for two Rh— individuals to have an Rh+ child. This fact is of importance in determining possible parentage.

Anti-Rh agglutinins are never normally present, but can be produced in some Rh— individuals by the introduction of Rh+ cells into the circulation. If an Rh— person of either sex is transfused with Rh+ blood, and especially if several transfusions are given, agglutinin formation may be stimulated. In an Rh— woman, pregnant with an Rh+ fetus (Rh+ gene inherited from an Rh+ father) agglutinins may be produced by the passage of the Rh+ fetal cells through the placental villi into the maternal circulation. Agglutinins which are present in the maternal blood either as a result of transfusions or pregnancy may pass through the placenta and cause agglutination and hemolysis of the red blood cells of the fetus. The changes characteristic of erythroblastosis result.

When agglutinins have once been produced they persist or are reformed during each pregnancy so that all subsequently conceived Rh+ fetuses will suffer from erythroblastosis. Agglutinins may be present in the blood of the mother and may affect the fetus even though they cannot be demonstrated by laboratory tests. Several investigators have recently reported that the blood of some immunized women contains an inhibiting substance which interferes with the *in vitro* action of the agglutinins. It is possible that the presence of the inhibitor substance is a sign of extreme immunization and may explain why the women whose fetuses are most severely affected are often those in whom anti-Rh agglutinins have previously been undemonstrable.

Many important facts have been established in the last five years concerning the relation of the Rh factor to

erythroblastosis. In approximately 10 per cent of all pregnancies, an Rh— woman bears an Rh+ child. Erythroblastosis occurs in about 0.3 to 0.4 per cent of new-born infants, or once in every 30 to 40 pregnancies where the wife is Rh— and the husband is Rh+.

Over 90 per cent of all women with infants suffering from erythroblastosis are Rh—. The seeming occurrence of the disease in the 10 per cent who are Rh+ may be explained by:

1. Sensitization to—
 - a. one of the Rh subgroups
 - b. Hr, a rare antigenic substance genetically related to Rh
 - c. A or B antigens (still not conclusively proved)
2. Error in diagnosis of the disease
3. Error in performing the Rh tests
4. Some as yet unknown cause

Erythroblastosis seldom occurs in a first pregnancy except when an Rh— woman has had one or more previous transfusions of Rh+ blood. In those rare cases where it does occur in the absence of a previous transfusion or pregnancy the disease is usually mild. After it once occurs all subsequently conceived Rh+ fetuses will be affected, all Rh— fetuses will escape. The disease frequently, but not invariably, becomes more severe with succeeding pregnancies; when a woman has once lost a child from erythroblastosis the majority of subsequently born Rh+ children also fail to survive; a child who does survive may show evidence of brain damage. The number of Rh— children conceived in subsequent pregnancies by women who have given birth to one infant with erythroblastosis is much lower than would be expected if 55 per cent of the husbands were heterozygous for the Rh factor*; it has

* The estimated genotypic ratio in a population mating at random is 37.54 per cent RhRh; 47.46 per cent Rhrh; 15.00 per cent rhrh. Among those who are phenotypically Rh+ the ratio is 44.7 per cent RhRh; 55.3 per cent Rhrh. In a random population of Rh— (rrhh) women married to Rh+ men (RhRh or RhRh) 27.65 per cent of the offspring should be Rh— (rrhh).

been suggested, therefore, that the homogygous Rh+ state of the father is associated in some unknown way with the initial production of the disease.

There is no known method of preventing erythroblastosis. The only treatment of value is symptomatic and consists principally in giving transfusions of Rh- blood to tide the infant over the period when it is destroying its own Rh+ cells. The recent suggestions that Rh+ cells are preferable to Rh- are not supported by adequate clinical observations, and the best evidence at the present time indicates that Rh- blood gives more favorable results. Only when Rh- blood is unobtainable should resort be had to Rh+ blood. Intraperitoneal or intramuscular administration of blood is without value. Iron and liver are of value in promoting the production of new erythrocytes, and general supportive treatment should be used as indicated.

When it becomes necessary to transfuse any Rh- individual, Rh- blood should always be used if possible. It is imperative that Rh- women who have given birth to infants with erythroblastosis receive Rh- blood, but since immunization may occur in either sex from multiple transfusions, it would be safest never to transfuse any Rh- individual with Rh+ blood. An additional problem presents itself in relation to transfusion of the female. It is possible for transfusions given in childhood or young womanhood to produce immunization and prevent an Rh- woman from ever bearing normal children by an Rh+ man. Unless generalized Rh testing becomes possible the increasing use of transfusions, as a result of the greater availability of blood in blood banks, is certain to result in an increasing incidence of erythroblastosis.

The Rh antigen was originally thought to be a specific uniform substance whose presence could be de-

tected by the use of a single anti-Rh agglutinin either human or animal in origin. It has since been shown to consist of several component parts. At least 8 variations in the antigenic nature of the Rh substance have been described, all believed to be allelic in character. They can be demonstrated by the use of three different anti-Rh agglutinins.

The agglutinins produced in rabbits and the type most commonly found in human beings clump the red blood cells of about 85 per cent of the white population of the United States, England, and Australia. Agglutinins have been observed, however, which show some variability in the percentages of bloods whose cells they agglutinate; outstanding among these are two types of sera which react with only 30 per cent and 70 per cent of bloods respectively. For the most part, cells which are agglutinated by the 30 per cent serum are also agglutinated by that giving a 70 per cent reaction, and the cells reacting with the 70 per cent serum usually react with the 85 per cent serum, while those which fail to react with the 85 per cent serum are also usually negative with the other two. If this were uniformly true all bloods could be divided into 3 Rh groups; unfortunately there are occasional variations, so that at least 8 groups must be recognized.

The occasional variables are of much less practical importance than they are of theoretic interest. For practical purposes an individual can be classified as Rh+ or Rh- according to the reaction of his or her cells to the standard anti-Rh serum. It is only important to remember that of two individuals who react positively to the 85 per cent serum, one may react positively to one or both of the other two sera, while the other may react negatively to one or both. In the case of the latter individual it might be possible for sensitization to occur from the introduction into

his circulation of blood which is positive to one of the sera to which his own blood reacts negatively; i.e., in spite of the fact that he is Rh+ to one serum an individual may still develop Rh antibodies against a portion of the Rh complex which he lacks, and consequently can be positive for one Rh antigen and at the same time possess antibodies against another Rh antigen.

The question has been raised concerning the desirability of discouraging marriage between Rh- women and Rh+ men. In one state legislature there has already been a bill proposed to make such marriages illegal, and at least one judge has found the inability of a couple to have children because of Rh incompatibility sufficient ground for divorce.

It is extremely difficult to arrive at an accurate figure for the incidence of erythroblastosis. During the last five and one-half years, 19,000 infants have been born at the Chicago Lying-in Hospital. Thirty of the deaths and 20 of the stillbirths were believed due to this condition, making the incidence of fatal cases approximately 1 in 380 births.

It has been suggested that the incidence is somewhat high because of the nature of the cases treated at this hospital, but in spite of this our incidence is lower than that reported from some other institutions and it seems a conservative figure.

In the United States in 1943 there were 2,934,860 births and about 78,485 stillbirths, making the total number of reported births slightly over 3,000,000. If the mortality from erythroblastosis was the same throughout the country as at the Chicago Lying-in Hospital, approximately 8,000 babies in the United States died during 1943 from this disease. In addition to those who died there were probably many of those who survived who were permanently handi-

capped by brain damage incident to the disease.

At least 90 per cent of the cases of erythroblastosis could be prevented if there were no matings between Rh- women and Rh+ men. The question to be decided is whether this potential salvage would compensate for the time, money, and personal sacrifice involved in universal Rh testing and prohibition of marriage between persons of incompatible blood groups.

It is extremely important that the cause of death be ascertained in every infant who is stillborn or who fails to survive. If erythroblastosis exists further attempts at childbearing on the part of that mother cause a needless physical, emotional, and economic loss. To condemn a woman to a barren existence, however, because of an erroneous diagnosis of erythroblastosis is as grievous a fault as allowing her to continue to bear dead infants. At the present time erythroblastosis frequently goes undiagnosed even in the presence of typical symptoms, and, on the other hand, is commonly indicted as a cause of death on inadequate grounds. Improved diagnostic acumen is needed both by clinicians and pathologists.

HEMORRHAGIC DISEASE

Hemorrhagic disease is a condition about which there has been much debate since it was first described by Townsend⁴ in 1894. He defined it as spontaneous external or internal bleeding occurring in new-born infants, unrelated to trauma, accident, or definite disease. Since that time this same definition has been widely used but has been variously interpreted by different investigators. Many have included infants with intracranial hemorrhage, and some have included many infants with severe asphyxia at birth. Others have excluded both of these groups, contending that intracranial hemorrhage is usually traumatic

and that the presence of asphyxia is directly contributory to hemorrhage. Such investigators have usually included as having hemorrhagic disease only infants with bleeding under the skin, into the gastrointestinal tract or other abdominal or thoracic viscera. The contention on the part of those who have included a wider variety of hemorrhage has been that although trauma or asphyxia might be responsible for a certain amount of bleeding, a coexisting hemorrhagic tendency might increase mild bleeding into a fatal hemorrhage.

Rodda⁵ in 1920 reported that infants with hemorrhagic disease exhibited a prolonged bleeding and clotting time and believed this could be shortened by the intramuscular administration of whole blood. He recommended the routine testing of bleeding and clotting time in order that infants manifesting these conditions might be treated and bleeding prevented.

Dam's discovery of vitamin K and the establishment of its relation to blood coagulation gave new impetus to the study of hemorrhagic disease. With the introduction of adequate methods for determination of prothrombin time, several investigators reported that infants with hemorrhagic disease had a marked prolongation of prothrombin time and that the administration of vitamin K caused a decrease in prothrombin time and a cessation of hemorrhage. It also soon became evident that although the prothrombin time is normal in almost all infants at birth it often becomes gradually prolonged and reaches a maximum on the second or third day of life. The prothrombin time subsequently becomes shortened and is ordinarily again normal by the end of the first week. It was also learned that by administering vitamin K to the mother during labor or to the infant immediately after birth, this prolongation of prothrombin time could generally be prevented.

As a consequence, the recommendation was made that vitamin K be given to all pregnant women during labor, or for days or weeks prior to delivery, and to all infants immediately after birth. Many investigators were extremely enthusiastic in their prophecies regarding the saving of life that would follow its generalized use. It was suggested that hemorrhage as a cause of death would become almost a thing of the past.

One of the first dissenting voices was that of Sanford,⁶ who, with his co-workers, reported no decrease in hemorrhagic manifestations among 800 infants who received vitamin K immediately after birth. Parks and Sweet⁷ gave vitamin K to 2,000 women during labor with no reduction in stillbirth and neonatal mortality rates. At the Chicago Lying-in Hospital⁸ over a 2 year period, 6,000 women were given vitamin K. The fetal and infant mortality during those years was compared with that during the subsequent two years when the vitamin was not given and no difference was found. Lehman⁹ has recently reported that, of 13,000 infants who received vitamin K after birth, the mortality from hemorrhage among those born alive at term was reduced 1.6 per 1,000 in comparison to a group of 17,000 who did not receive the vitamin.

Most of the series of cases in which mortality rates appeared to have been appreciably decreased by the use of vitamin K were relatively small and at the present time most of the evidence seems to indicate that little saving of life in the new-born period can be expected from the routine administration of vitamin K to mother or infant.

It appears, however, to have value in the treatment of gastrointestinal hemorrhage, and should be given any infant with such bleeding without delay. Moreover, it should be administered to any infant with demonstrable or suspected bleeding on the possibility

that the prothrombin time may be prolonged.

It may be concluded that occasional infants show spontaneous hemorrhages which are associated with a prolonged prothrombin time and that such hemorrhages will cease when the administration of vitamin K has brought the prothrombin time to a normal level. Hemorrhages due to any other cause are unaffected by vitamin K. The routine administration as a prophylactic procedure does not seem warranted.

RUBELLA AND CONGENITAL MALFORMATIONS

The fact that viruses are easily propagated in embryonic tissue has been known for many years, but not until Gregg¹⁰ in 1942 found an association between rubella in early pregnancy and congenital defects of the eyes and heart, was it recognized that virus diseases might be the cause of certain human malformations.

Gregg reported 78 infants with congenital cataracts, all but 10 of whose mothers gave history of rubella during early pregnancy. The majority of these infants were small, poorly nourished, and were difficult to feed. In all but 16 the cataracts were bilateral and in at least 44 there was some evidence of a cardiac malformation. All were born in Australia and most of the mothers had been exposed to rubella during a single epidemic.

The apparent relationship between rubella in early pregnancy and the presence of congenital cataracts in the new-born aroused immediate interest in the problem in Australia and, under the auspices of the National Health and Research Council, Swan and his co-workers¹¹ began a widespread investigation. They were able to locate 57 infants whose mothers gave a history of some exanthematous disease during pregnancy. Of 25 women who had had rubella in the first 2 months of preg-

nancy, all offspring suffered some type of malformation; malformations were also present in 4 infants of 8 women who had had the disease in the third month, and in only 2 of 12 who had had it later. In the total group there were 14 infants with eye defects (all but one of which were cataracts), and of these, 9 also had heart lesions, 3 were mentally defective, and 1 had a club-foot. In all there were 17 infants with heart defects, 6 of whom were otherwise normal. There were 4 infants with cataracts in whom there was no history of maternal infection.

In a subsequent paper, Swan and his coworkers¹² reported 13 additional women affected with rubella in the early months of pregnancy, 11 of whose offspring had congenital defects. These consisted largely of cataracts, microcephaly, and deaf mutism. In 1944 Reese,¹³ Rones,¹⁴ and Erickson¹⁵ each reported a few cases in the United States similar to those observed in Australia. Reese recorded 3 cases of congenital cataracts, all associated with cardiac disturbances, in infants whose mothers had had rubella in early pregnancy. Rones reported 2 infants with congenital cataracts whose mothers had had the infection during the second month of pregnancy, 2 with glaucoma where the infection had occurred during the third month. Erickson observed 10 infants with cataracts and 1 with microphthalmia. Ten mothers had had rubella in the first 2 months of pregnancy, 1 at 2½ months. Nine appeared to have congenital cardiac defects.

At a meeting of the New South Wales Branch of the British Medical Association in December, 1944, another manifestation of maternal rubella was discussed. Carruthers¹⁶ stated that, with the help of the health department, 147 infants with congenital malformations had been found, and that of these 116 were deaf. Among the 102 born to women with definite histories of rubella

in early pregnancy, 74 were deaf-mutes and 14 gave evidence of congenital heart disease. He described in detail 17 infants with deaf-mutism who were under his own care. None had heart lesions or cataracts. Eleven were physically stunted and 3 were microcephalic.

Gregg¹⁷ at the same meeting also reported having examined several infants who were deaf-mutes but who lacked evidence of ocular defects, and stated that he had previously reported 8 infants who had been observed after the publication of his original paper. All had eye disturbances and additional abnormalities had consisted of heart disease in 6, and deafness in 3.

In discussing the papers by Caruthers and Gregg, Vickery¹⁸ presented data on 21 infants with variable degrees of deafness. Twenty mothers had had rubella (and the other was presumed to have had it) during the first 3 months of pregnancy. Thirteen gave evidence of congenital heart disease; all were nervously unstable, but none had eye defects.

Dr. E. S. A. Meyers at the same meeting commented on the fact that over 200 children had been made defective by a single epidemic of rubella (78 cases reported by Gregg and 145 more collected by the Health Department of New South Wales).

It appears that three principal defects are to be found in children whose mothers have had rubella during early pregnancy. These consist of cataracts involving the central part of the lens, ear defects producing deaf-mutism because of the almost complete loss of hearing occasioned by a sacculo-ocular type of degeneration, and cardiac disturbances due to interventricular defect, or patency of the ductus arteriosus.

Almost all women with rubella in the first two months of pregnancy give birth to defective children; when the disease occurs later the infant is less prone to

be affected, but eye defects have followed its occurrence in the third month, and ear defects its occurrence in the fourth month.

Almost all of the cases reported from Australia have been associated with epidemics of rubella. The relatively few cases reported from any other country may indicate either that within recent years the disease has not occurred in epidemic form among young adults or that the perspicacity of the Australian investigators has led them to make an association between maternal rubella and congenital defects in the offspring which other observers have overlooked.

If a single epidemic in Australia produced more than 200 defective children, the prevention or control of similar epidemics in other parts of the world becomes a challenge to all individuals interested in public health.

CONCLUSION

The discovery of vitamin K, the recognition of the Rh factor, and the establishment of the relation of the rubella virus to malformations, constitute important advances in knowledge concerning conditions affecting the fetus during the intrauterine period and the early days of life. All of these discoveries are excellent examples of the spectacular results which may follow the correlation of fundamental observations with clinical problems. They point the way for further advances and illustrate the necessity for the close integration of all fields of scientific investigation.

Tuberculosis Case Finding with Mobile Photo-Roentgenographic Unit in Sumner County, Tennessee*

R. B. TURNBULL, M.D., W. B. FARRIS, M.D., AND
MILDRED PATTERSON

Sumner County Health Department, Gallatin, Tenn.

SINCE 1929 tuberculosis case finding clinics have been held regularly by the Sumner County Health Department. From 1929 to July, 1939, this service was furnished through the Division of Tuberculosis Control of the Tennessee Department of Public Health and consisted of clinics held once or twice a month in Gallatin for the examination of known cases, contacts to such cases, and individuals referred by private physicians because of symptoms. Any resident of Sumner County was eligible for examination upon referral by his family physician. With the assistance of the Commonwealth Fund, a special Tuberculosis Control Program was inaugurated in July, 1939, which was aimed particularly at the treatment of tuberculosis in the absence of adequate hospital facilities. Sufficient personnel and equipment were supplied to carry on an intensified case finding program with the treatment program. In this program four x-ray clinics a month were held in Gallatin, the county seat, and one each in Portland and Westmoreland, the two other largest community centers in the county.

The number of cases of reinfection tuberculosis in need of collapse therapy and other treatment was sufficient to warrant the expenditure of funds under

the control program. It was felt, however, that the proportion of early cases of tuberculosis discovered through the Health Department clinic was lower than it should be, and that another case finding method should be tried. Through a gift of the Commonwealth Fund, the Division of Tuberculosis Control of the Tennessee Department of Public Health purchased a mobile photo-roentgenographic unit for use in Tennessee; and Sumner County is one of the first counties making use of this unit in the extension of the case finding program. The Sumner County Medical Society has given blanket permission for x-ray examinations on the mobile unit. Since both case finding services have run and will continue to run concurrently, it is of interest to compare the numbers of people reached by each method and the comparative results in actual cases found.

There is considerable difference in the cost of the two services. The 14" x 17" flat film used in the Health Department clinic is more expensive than the 4" x 5" stereoscopic film used on the mobile unit. The usual clinic load in the Health Department clinics is approximately 30 per clinic day, while on the mobile unit 250 to 350 persons can be examined in a clinic day. The lower unit film cost and accessibility to larger groups of people during a clinic session makes the mobile unit case finding serv-

* This investigation was made possible by the financial support of the Commonwealth Fund

ice less expensive than the Health Department clinics.

The small film is used as a screening process for the designation of definite or suspicious pathology. Cases with suspicious or definite tuberculous lesions are reexamined in special clinics using 14" x 17" film. The final interpretation is made by two clinicians using both films and other diagnostic aids.

The mobile unit was scheduled for five visits to Sumner County between October 1, 1944, and May 31, 1945. These visits varied in length from 2 to 5 weeks. During subsequent months the mobile unit will be scheduled for visits to community centers in the county until the entire population has been given an opportunity to have an x-ray examination.

The purpose of this evaluation is the presentation of the comparative effectiveness of the mobile unit and the Health Department clinic as case finding services. The material has been divided into three sections: (A) Persons Examined on Mobile Unit and in Health Department Clinic, October 1, 1944, through May 31, 1945; (B) Results of Case Finding in School, Industry, and Community Groups; and (C) Extent and Activity of Cases of Reinfection Tuberculosis.

A. PERSONS EXAMINED ON MOBILE UNIT
AND IN HEALTH DEPARTMENT CLINIC,
OCTOBER 1, 1944, THROUGH MAY 31,
1945

Through Health Department activities in the past five years the citizens of Sumner County have become aware of the tuberculosis problem. In general, the people are very receptive of this new x-ray program. The first work in the initiation of this program was in organized groups. In the two shoe factories the personnel departments were contacted and were responsible for the organization of the procedures for examination of their employees. In the other indus-

tries the program was explained to plant managers and an opportunity was provided for a discussion with the employees of the importance of x-ray examinations. In all industries the response was excellent. The high schools were handled in the same manner as the industries, with the program presented to the students. For the general community survey of Gallatin, which followed the work in industries and high schools, the program was explained to many groups. These included civic and home demonstration clubs, Parent-Teacher Association, the churches, the County Court, and the City Council. Articles in newspapers, reels in movie houses, and hand bills distributed by Scouts and airplanes were used in the pre-survey publicity. Since the number of clubs was limited in Hendersonville, the second community visited, hand bills were mailed to all rural box holders in this area. The results of examinations in these two community centers only are included in this preliminary report.

During this 8 month period 5,656 x-ray examinations have been made on the mobile unit and in the Health Department clinic. Included in the total were 138 individuals who were not residents of Sumner County. The mobile unit reached 4,825 persons through the survey of five industrial plants, three high schools, the city of Gallatin, and the area of Hendersonville. The Health Department clinic furnished examinations for 831 other persons from all over Sumner County through its established x-ray clinics.

The survey includes examination of persons 12 years of age and over. According to the 1940 census, the population of Sumner County in this age group was 25,043. Thus far 5,518, or 22.0 per cent of the population of the county (excluding non-residents), have been x-rayed: 4,715, or 18.8 per cent, have been examined on the mobile unit

* Less than 0.05 per cent

and 803, or 3.2 per cent, in the Health Department clinic. Since one entire visit of 5 weeks' duration was devoted to the city of Gallatin, it was hoped that a high percentage of its citizens would be x-rayed. A total of 2,291, or

62.0 per cent of the city residents, did take advantage of this opportunity. The mobile unit attracted 2,111, or 57.1 per cent, of the residents of the city, while the Health Department clinic served 180, or 4.9 per cent. The white females

CHART A—Percentage of Population Examined in School, Industry, and Community Groups on Mobile Unit, and in Health Department Clinic, by Age

were the largest group with 1,090, or 79.2 per cent, x-rayed. The white males had the second largest number and percentage examined with 734, or 60.8 per cent. The colored females had 267, or 47.1 per cent, examined, and the colored males 200, or 36.6 per cent. The percentages for the white and colored male groups would be considerably higher if account were taken that approximately 10 per cent of the males were in the armed services. The response of the colored population was disappointing, particularly in view of the fact that the mobile unit was moved to the two colored sections of Gallatin especially to attract this portion of the city's residents.

The number and percentage by age group of the 5,656 individuals reached in this case finding program through surveys of school, industry, and community groups on the mobile unit and in the Health Department clinic, are given in Table 1. Seven hundred and thirty-two of those examined on the mobile unit were high school students and teachers, 1,352 employees in industries, and 2,741 persons in the general population. Chart A shows by age groups the percentages of population examined in the first part of this program through school, industry, and community surveys by the mobile unit and in the Health Department clinic. From Table 1 and Chart A the differences in the age distribution of the

populations of the four groups are apparent. The community survey resulted in the examination of a relatively large proportion of adults 25 years of age and over. The industrial survey reached young adults. The high school group consisted of persons under 20 years of age with the exception of a few teachers. The Health Department clinic, however, served persons of all age groups. The age composition of these groups needs to be considered in the evaluation of this case finding program.

B. RESULTS OF CASE FINDING IN SCHOOL, INDUSTRY, AND COMMUNITY GROUPS

The Health Department clinic serves two different purposes: The examination of persons as a case finding procedure, and the reexamination of persons known to have and suspected of having reinfection tuberculosis. In order to compare the results of these case finding procedures, it was necessary to use only the first examinations in the Health Department clinic. There were 500 people 12 years of age and over who were examined for the first time in the Health Department clinic during these 8 months, and the results of their examinations will be used for comparison with the results from the mobile unit.

Of 5,325 x-rays made on the mobile unit and in the Health Department clinic, 190, or 3.6 per cent, showed evidence of clinical pulmonary tubercu-

Community	2,741	103	3.8
Health Department Clinic	500	44	8.8

losis. Thus far in this program no significant difference was noted in the prevalence of tuberculosis in the white and colored groups examined. In the population x-rayed, 5, or 0.7 per cent, of the persons examined in the high school group, were found to have tuberculosis, 38, or 2.8 per cent, of the industrial employees, and 103, or 3.8 per cent, of the persons in the community group examined on the mobile unit were found to have tuberculosis. The Health Department clinic found 44 cases, or 8.8 per cent, in the persons examined for the first time. Table 2 and Chart B show clearly that the Health Department clinic is still the most efficient case finding method. The community survey was second most efficient in discovering tuberculosis, with the industrial survey following as third, and the high school survey as the least efficient.

In Table 3 appear the number and percentage of persons examined and found to have reinfection tuberculosis in the school, industry, and community groups on the mobile unit, and in the Health Department clinic by age group. The Health Department clinic has the highest percentage of cases for each age group with the exception of the small group under 15 years of age. In examination of the general community population on the mobile unit and in the Health Department clinic the highest percentages of cases were found in the age group 55 years and over, with 11.3 per cent in the community group and 35.1 per cent in the Health Department clinic, found to have reinfection tuberculosis. It is evident that the examination of persons 55 years of age and older is productive in the discovery of tuberculosis in this area.

The percentage of examined population with reinfection tuberculosis by age group is shown in Chart C for the mobile unit and the Health Department clinic. In the group examined on the mobile unit, the percentage of cases increased with age, which was due principally to the accumulation of inactive cases. The percentage of active cases from these examinations on the mobile unit did not vary greatly by age group. The number of examinations made by the Health Department clinic in this period

has been small, which might account for some of the variations. The percentages increased generally with age, the highest occurrence being in the age group 55-64 years. The percentage of active cases found in the Health Department clinic also is highest in this age group, being higher than the percentage with active tuberculosis found on the mobile unit in the same age group. More active cases of reinfection tuberculosis would be expected among persons who are examined because of contact to

CHART C—Percentage of Examined Population with Reinfection Tuberculosis and with Active Reinfection Tuberculosis Found on Mobile Unit and in Health Department Clinic, by Age

known cases and/or because of clinical symptoms than among other groups without such characteristics.

C. EXTENT AND ACTIVITY OF CASES OF REINFECTION TUBERCULOSIS

Through the case finding methods employed—the mobile unit and Health Department clinic—190 cases of reinfection tuberculosis were found. The extent and activity of the 146 cases from the mobile unit and 44 from the Health Department clinic are given in Table 4.

Included in the 146 cases from the mobile unit were 55 previously known cases and 91 cases not previously known to the Health Department. Thus nearly two-thirds of these cases were not known to the Health Department. There were in all 28 active cases, and of these 20 were new. Of these 20 active cases, minimal cases numbered 16, moderately advanced 3, and far advanced 1. Seventy-one of the 118 inactive cases were new, of which 55 were minimal, 15 moderately advanced, and 1 far advanced.

TABLE 4

Extent and Activity of 190 Cases of Reinfection Tuberculosis Found on Mobile Unit and in Health Department Clinic

Extent and Activity	Total			Mobile Unit			Health Dept. Clinic	
	Cases Found	New Cases		Cases Found	New Cases		New Cases	
		Number	Per cent		Number	Per cent	Number	Per cent

Moderately advanced inactive	32	20	14.8	27	15	16.5	5	11.4
Minimal inactive	107	72	53.3	90	55	60.4	17	38.6

CHART D—Percentage Distribution of New Cases Found on Mobile Unit and in Health Department Clinic, by Extent and Activity

Percentage distributions of the new cases found on the mobile unit and in the Health Department clinic are shown in Chart D and Table 4 according to extent and activity. Of the 91 new cases found on the mobile unit, 20, or 22 per cent, were active, while of the new cases found in the Health Department clinic, 22, or 50 per cent, were active.

Of the new active cases in the Health Department clinic, 77 per cent were far advanced and moderately advanced, while of those found on the mobile unit only 20 per cent were far advanced and moderately advanced. It is noteworthy that minimal cases are discovered, and discovered relatively frequently, through the examination of apparently well people in these surveys of the general population. During this period of time, 16 new minimal active cases were discovered through the mobile unit and only 5 in the Health Department clinic.

One of the main objectives of the tuberculosis control program since its inception has been the adequate treatment of known cases of reinfection tuberculosis. The visits of the mobile unit to Sumner County have been scheduled so that sufficient time was allowed for institution of treatment and follow-up procedures by the Sumner County Health Department. Hospitalization and treatment of new active cases have been instituted promptly. It is felt that the success of the case finding program by use of the mobile unit is due to the fact that both case finding and treatment services are being carried on concurrently.

DISCUSSION

In the course of the work in the Health Department clinic in Sumner County, a relatively high proportion of the new cases of tuberculosis discovered through referral of persons with symptoms and of contacts had tuberculosis in the advanced stages. There-

fore, it seemed desirable to extend case finding activities to the so-called healthy population of the county to find persons with minimal tuberculosis before symptoms had developed. In order to reach the general population, a mobile photo-roentgenographic unit using 4" x 5" film, a gift of the Commonwealth Fund, was made available by the Tennessee Department of Public Health.

The initial work in this program with the mobile unit was with organized groups—the large industries and high schools. This service is being extended gradually to all sections of the county in order that satisfactory control and treatment procedures can be instituted promptly. In this paper the results of the program in industries and high schools and in the two communities are reported.

The comparison of the results of this program using the mobile unit with those from the routine chest clinic indicates the value of carrying on both types of services. Although the Health Department clinic is effective in the discovery of clinical tuberculosis, this case finding method needs to be supplemented in order to find tuberculosis before the disease has become advanced and has been spread to others. During this 8 month period, in addition to 44 new cases discovered in the Health Department clinic, 91 other new cases were found through the mobile unit. The community survey, which was the second most effective method of finding tuberculosis, resulted in the discovery of tuberculosis in the older as well as the younger age group.

It is noteworthy that 80 per cent of the new active cases found by the mobile unit were in the minimal stage, while of those discovered in the Health Department clinic 77 per cent were in the advanced stages of the disease. Cases in the early stages have the best opportunity for recovery. Thus the mo-

mobile unit has been a valuable aid in the discovery of minimal tuberculosis in the apparently healthy population of the county.

SUMMARY

1. The results of case finding through surveys in high schools, industries, and in communities in Sumner County through five visits of a mobile photo-roentgenographic unit have been compared with the results of case finding in the routine scheduled clinics of the Health Department.

2. The age distribution of the population reached in these groups differed considerably, with the community survey reaching adults in all age groups.

3. In the population x-rayed, only 0.7 per cent of the high school group were found to have clinical tuberculosis. The percentages were higher for industrial employees (2.8) and for persons examined in the community survey (3.8). The age compositions of these groups were responsible for the differences. In the Health Department clinic 8.8 per cent of the persons examined for the first time

because of symptoms or contact had tuberculosis.

4. The percentages of the examined population found with reinfection tuberculosis increased with age, with very high prevalence rates for those 55 years of age and over.

5. Through these case finding methods, 190 cases of reinfection type tuberculosis were found: 146 by the mobile unit, of which 91 were new cases, and 44 new cases through the Health Department Clinic. Thus the mobile unit was a valuable aid in the discovery of tuberculosis in Sumner County. Of the new active cases discovered by the mobile unit, 80 per cent were minimal, while of the new cases in the Health Department clinic only 23 per cent were minimal.

ACKNOWLEDGMENT is made of the assistance of E. F. Harrison, M.D., Acting Director of the Division of Tuberculosis Control, Tennessee Department of Public Health, during the period covered by this report.

Acknowledgment is also made of the assistance of Ruth R. Puffer, Dr.P.H., Director of Statistical Service of the Tennessee Department of Public Health.

ONE REASON WHY WE ASK FOR BACK JOURNALS

We have been asking readers of the JOURNAL who have back copies of the magazine which they no longer need to send them to the office. These copies are being used to complete volumes which are then sent to devastated libraries and to individuals desperately seeking to catch up on professional literature they have missed during war years.

The following letter tells more eloquently than we can how valuable these old Journals can be.

"Dear Sirs:

Way back in 1941, before the outbreak, I used to receive copies of our Journal as member and subscriber. That was shortly before I was mobilized by the Philippine Army and inducted into the service of the United States Forces in the Far East (USAFFE of MacArthur).

After the fall of the Philippines and during the Jap Occupation, I've missed our Journal. As a guerilla, I've been longing for some copies in our mountain ramparts. I couldn't even get my old copies as my house and everything in it, including the Journals, were all burned by Japs.

Now that all is well, I shall be glad to hear from you.

Sincerely,

....."

Control of Typhus in Italy 1943-1944 by Use of DDT*

LT. COL. CHARLES M. WHEELER, SN.C., AUS

Member United States of America Typhus Commission, Washington, D. C.

DURING the winter of 1943-1944 a severe epidemic of typhus fever threatened the population of Naples and Southern Italy. When Allied Forces landed in that country in September, 1943, cases of typhus had been reported dating back as early as March of that year. In December a sharp increase in the number of cases occurred and deep concern was felt for the safety of Allied troops and the Italian civilian population. Consequently immediate steps had to be taken to institute proper control measures.

HISTORY OF TYPHUS FEVER IN ITALY

Italy appears to have repeatedly escaped the ravages of severe typhus epidemics which have periodically swept over eastern and western Europe, Russia, the countries bordering the eastern end of the Mediterranean Sea, Egypt, and North Africa. Records show that the principal rickettsial infection in Italy up to 1915 was attributed to *Rickettsia conori*, the causative organisms of Boutonneuse fever which is transmitted by a dog tick, *Rhipicephalus sanguineus*.

During the 10 year period, 1915-1924, a total of 923 cases of epidemic

louse-borne typhus were reported to have occurred in various parts of the country. The greatest number of cases occurred in the year 1919 following the general resettlement migration of peoples all over Europe after the cessation of hostilities of World War I. The incidence of typhus fever dropped rapidly during the next decade, 1925-1934. A slight outbreak of the disease occurred in 1926 and 1927 but soon disappeared, and for the remaining seven years no cases of louse-borne typhus were recorded.† This apparent absence of typhus in Italy continued for another 8 years broken only by the threatened severe epidemic of 1943-1944. Thus the general population of Italy apparently had not known typhus for a period of 15 years and consequently was most susceptible.

Available records show that the first cases of typhus reported in Italy occurred in the city of Bari in March, and in Aversa in April, 1943, with other scattered cases in several small villages in Southern Italy. In the city of Naples the first authentic case was reported in July, 1943.

Many theories have been formulated concerning the possible source of typhus fever in Italy. None has actually been confirmed but in the absence of final reports, refugees entering Italy from the Balkan countries and Italian Prisoners

* Based on a paper presented before the Epidemiology Section of the American Public Health Association at the Seventy-third Annual Meeting in New York, N. Y., October 3, 1944.

From the United States of America Typhus Commission, War Department, Washington, D. C.

† Bull. Health Organ. League of Nations, X, 1, 1943; this bulletin shows 15 deaths due to typhus over a 5 year period, 1930-1934.

of War returning from Tunisia apparently brought the infection with them and undoubtedly introduced the disease at several points in Italy.

TYPHUS IN NAPLES

Following the original introduction of typhus into a practically non-immune population, the incidence of cases in Naples rose rather rapidly during the months of November and December, 1943.

Records indicate that during the late spring and summer months of 1943, typhus had been simmering insidiously in Naples. As colder weather approached reported cases became more frequent. In October, 29 cases occurred; in November, 61 persons had contracted the disease, and by December 5, 26 new cases had been reported. This number, in comparison with only 2 cases reported during the first 5 days of November, gave warning and forecast the outbreak of a severe epidemic as the winter progressed. By December 15, 83 cases had been reported in Naples. From 83 cases by the middle of this month, the number mounted to 288 for the latter half of the month, a total of 371 cases for December.

This was the picture of the case incidence of typhus in Naples shortly before the United States of America Typhus Commission was placed in charge of the control of the epidemic. The picture of conditions in Naples and, in fact, all of Southern Italy, was in complete harmony with descriptions of the classical spread of typhus fever epidemics of former years.

In Naples estimates of the civilian population in December, 1943, varied between 750,000 and 1,000,000 persons. In addition to this huge population were hundreds of Allied soldiers, returning Italian civilians, and refugees from other war-torn parts of Italy and from across the Adriatic. Living conditions in general were congested and unsani-

tary. Telephone, transportation, and other public utilities were disrupted. Medical personnel for the most part were in the army. Food was scarce, "black market" prices exorbitant, and undernourishment of the inhabitants of Naples was striking. The people were confused, frightened, cold and hungry. Leadership had changed so fast in recent weeks that the average individual scarcely knew which way to turn nor just whom to believe. The recent bombings and terrorist activities of the Germans, and then bombings by Allied Forces kept the people in a constant state of fear and anxiety. At the first wail of the air-raid alarm thousands of people would pour from their homes and crowd into the numerous air-raid shelters scattered throughout the city, of which there were 385.

The air-raid shelters (*ricoveri*) were most interesting. The hills of Naples on which the city is built are of a limestone formation honey-combed by huge caverns. Long, dark or dimly lighted winding staircases or sloping tunnels led down into many of these caverns to a depth of as much as 75 to 100 feet. In some of these tremendous underground rooms thousands of people were found living under quite primitive conditions. Some of the inhabitants were living more comfortably than others, having brought along with them some of their household effects, their beds and bedding. One series of caves was particularly impressive. These were arranged in three levels opening onto the face of a limestone cliff. The rooms extended more than 100 yards back into the cliff, with arched ceilings as high as 50 to 75 feet. Along the walls in the lower of the three rooms people had erected small wooden shacks, one to three stories high. As many as 3,000 persons had lived in these 3 caverns at one time or another. The second- and third-level rooms housed fewer persons and the homes here ranged from stone

"mansions" to wood, metal, and bur-lap covered shacks.

Not all of the ricoveri were formed from natural caverns. Many small shelters were constructed of reinforced concrete and located along the railroad yards, dock areas, etc. These shelters were small, poorly lighted, and very poorly ventilated. No sanitary facilities were available in most of them and people lived in their own filth and grime, dirt and disease. In many of these shelters typhus cases and corpses of persons dead from typhus were found, and for each one found several persons as "contacts" were free to leave the shelter and scatter infective lice to other parts of the city.

In Naples one instance of probable wholesale broadcast of infected lice is interesting. In the huge three-level grotto near *Marginella* railroad station two cases of typhus were discovered by the night control crews. The patients, a mother and her son, were in a small, one-room wooden shack deep inside the second-level cavern. Both were seriously ill and were in the only bed in the room; both were fully clothed but disgustingly and pathetically filthy, and heavily infested with lice. The father of the family was able to work during the day but slept at night in this same bed. Upon examination of his clothing he was found to be heavily infested as well. His occupation at the time was driving a horse and cart, delivering various articles to homes in scattered parts of the city. These three persons were isolated in a hospital; and shortly afterward the father also developed the disease. One wonders how many cases of typhus this man may have caused.

Many of the homes visited were nearly as filthy and crowded as the ricoveri. In some instances two and three families were living crowded into two average-size rooms in a dark, damp cold building. Children were dirty and poorly clothed. With no soap, no fuel,

and poor food there was little incentive or interest among many to try to keep clean.

No definite observations were made in the beginning concerning the extent of the louse infestation among the civilian population of the city. Assurance was given that it was widespread and the percentage of infestation high. A few counts made on clothing of persons admitted to the Cotugno hospital early in the epidemic substantiated this assurance.

The following summarizes the reasons for the spread of typhus in Naples:

1. Introduction of typhus into a non-immune population
2. Crowding and overcrowding of people in homes and air-raid shelters
3. Intensive and widespread infestation-with body lice
4. Scarcity of proper kinds of food
5. Bathing facilities lacking or out of order
6. Scarcity of fuel
7. Lack of adequate medical care, hospitalization, and medical supplies
8. Little or no soap available
9. Lack of proper warm clothing and sound shoes among the poorer classes
10. Disruption of water, light, and sewer systems
11. Demoralization of transportation and communication systems
12. Confusion of people due to lack of proper leadership in all city civil government branches, including the Health Department

THE TYPHUS CONTROL PROGRAM

The development of three dusting powders lethal to lice (MYL and DDT in the United States, and AL-63 in England); the demonstration in the laboratory and in the field of the effectiveness of these powders in the control of lice; and the arresting of small typhus epidemics in native villages of Mexico, Algeria, and Egypt through the use of these powders were proof that the use of louse powder in the developing typhus emergency in Italy was the control method of choice in the field.

Methods of application of powder had been studied by various groups of

investigators, particularly the Rockefeller Foundation Typhus Team in collaboration with the Office of the Chief Surgeon, North African Theater of Operations. The procedure adopted for the application of powder to the clothing of infested individuals was speedy, economical in the amount of powder used, and eliminated the necessity for the removal of the clothing from the body of the person to be dusted. Essentially the procedure consisted of forcefully blowing powder, by hand-dusters or power-dusters, between the layers of clothing worn by the individual and between the innermost layer of clothing and the skin of the body. This was accomplished by a uniform technique, inserting the nozzle of the duster up the sleeves, down the neck, (both front and back), around the waist-line, and into the crotch area of clothing. Hair and any cap or hat were dusted thoroughly. An infested person properly dusted is no longer a menace to others and will remain so for a period of at least two weeks, at the end of which time he should be redusted. Approximately 1 to 1½ oz. of powder per person is sufficient to insure the thorough dusting of all clothing worn.

Actual dusting operations were instituted on December 15, 1943, by a dusting team previously trained by a member of the Health Commission of the Rockefeller Foundation. This team of workers dusted all outbound passengers boarding a train scheduled to leave Naples for Bari. The following day, December 16, contact dusting teams were organized and sent out to addresses of reported cases of typhus emanating from homes or institutions. On the night of December 27, the first dusting of persons living in air-raid shelters was undertaken. In addition to their regular dusting duties, each team was instructed to report any new cases or suspected cases of typhus. These teams discovered many new

cases which previously had not been reported to nor isolated by civil health authorities. The importance of proper case finding and reporting was so apparent that a special case finding section under Major R. L. Cherry, M.C. (AUS) of the Allied Control Commission was organized. The case finding and dusting operations were severely handicapped for the lack of proper assistants and dependable transportation.

Before the United States of America Typhus Commission was charged with the responsibility for control on January 3, 1944, many plans had to be drawn up and their values discussed. By December 26, 1943, the typhus control program, approved by the War Department, provided for six operational sections. Four of these sections were utilized from the outset, namely:

1. The case finding section
2. The contact delousing section
3. The mass delousing section
4. The immunization section

These four sections were in operation a few days before the fifth section, the flying squadron, became active. Later in the month of January a refugee delousing section was established to complete the table of organization as planned.

THE CASE FINDING SECTION

The case finding section was reorganized by and in charge of Major J. C. Snyder, M.C. (AUS) (now Lt. Col.), assisted by Major R. L. Cherry, M.C. (AUS) and 8 Italian-speaking U. S. Army physicians. Up to January 3, 1944, cases and suspects had been reported to the AMG Health Service for the City of Naples. These reports came in from various sources, with duplications in many instances. It was difficult to be sure that the cases reported were actually authentic cases of typhus fever until diagnoses were confirmed at the Cotugno Infectious Dis-

eases Hospital. However, not all cases were brought to this hospital and the problem was to discover whether these reported cases were actually typhus or some other disease easily confused with typhus in the early stages. Such was the job of the case finding section at the very beginning. Through the untiring efforts of Lt. Col. Snyder, this situation was gradually untangled and all parties concerned agreed to the proposition that the official daily list of typhus cases released by the Health Department be made up only from names of actual cases or definite suspects diagnosed either by the Cotugno Hospital staff physicians or by one of the U. S. Army physicians connected with the Typhus Commission. By intensive investigation of the back-log of reported cases by the U.S.A. Typhus Commission doctors, a gradually clearing picture of the situation began to take place, so that by January 10, 1944, this back-log of cases had been checked and case finding was put on a more logical basis.

Higher authorities directed that General Fox and the U.S.A. Typhus Commission be given the responsibility of typhus control and the Allied Military Government be responsible for ambulance, hearse service, isolation, hospitalization, and care of cases, including the steam sterilization of the clothing of cases admitted.

Organization—The work of the case finding section was accomplished through eight case finding teams, each team being in charge of a U. S. Army physician, assisted by an Italian nurse. Later in the work it was found desirable to add two persons to serve as dusters to each team. These people were transferred from the contact delousing section. A weapons carrier and driver served each team. Thus every case finding team was an independent unit.

Duties—The duties of the teams were:

1. Extensive and intensive case finding
2. Dusting of immediate family contacts as well as the patient or corpse
3. Isolation of patient (summoning ambulance)
4. Reporting of corpses found and summoning the hearse

Operation—In order to facilitate the location of addresses of reported cases, by agreement and coöperation with the contact delousing service, the city was arbitrarily divided into zones. These zones were outlined and marked on a large map of the city. Copies of this map were distributed among the other working sections of the Typhus Commission, and other copies sent to the Health Office of the AMG. As cases were reported, names, addresses, and map-reference zones were written on individual case history cards. These cards were then grouped by zones and given to the physician in charge of the team responsible for case finding in the zones assigned to him. At each address, if the case reported was a definite case of typhus or a suspect, this person was immediately dusted with the insecticidal powder by the dusters of the team, ordered to be hospitalized, and an ambulance summoned. In addition the immediate family contacts, living in the same room or house, were similarly dusted. Beds, bedding and extra clothing were also treated. In the meantime the nurse of the team was busy obtaining names of all of the persons of the family. These names were recorded on the case history card. The temperatures of all persons of the family were taken at the time of the visit.

Any person showing an elevation in temperature was placed under observation. If any suspicion of typhus was noted among these persons, they were ordered to be hospitalized at once. Mistakes of diagnosis were certain to occur, but a mistake on the safe side was not detrimental in this program. If a corpse was discovered, the clothes and

the body were dusted and the hearse summoned.

As each team reported back to headquarters, the patients' names, the names of the immediate family of each patient, addresses and map-reference zones were transferred to another card. This second card was given to the contact delousing service for further action.

CONTACT DELOUSING SECTION

Organization—The contact delousing service was reorganized and placed in charge of Major C. M. Wheeler, Sn.C. (AUS). The purpose of this section was to apply lousicidal powder to the bodies, clothing, extra clothing, beds, and bedding of definite or suspected typhus patients and contacts reported by the case finding section. At first no distinction was made between persons termed "contacts." After working with cases and contacts it was soon found that persons as contacts of typhus cases fell into three general classes: (a) contacts found in the *home* or in the immediate neighborhood, (b) contacts of cases discovered in *institutions* (such as prisons, hospitals, etc.), and (c) contacts occurring in the *air-raid shelters*. In order to deal more effectively with these three types of contacts the contact delousing section was organized to include three services; namely, the case-contact service, the "special" service, and the *ricoveri* service.

Each of these three services was in direct charge of a United States Army Officer assigned to, or a member of, the Typhus Commission. Each officer was assisted by an American (bi-lingual) civilian physician.

THE CASE-CONTACT SERVICE

Organization—The field working units consisted of the following personnel and equipment:

1. Squad—one nurse and two male dusters

2. Team—2-3 squads, depending upon the assignment of work

3. Weapons carrier and an enlisted man as driver

Duties—The duties of the dusting teams were as follows:

1. Continued case-contact dusting within the home or building in which cases had occurred

2. Focal dusting of all persons in dwellings within a prescribed given area in order to effect a clear area around the home

3. Reporting of all new suspects or new cases found

Operation—The cards given to this service daily by the case finding section were sorted as to map-reference zone and distributed among the six team leaders of each of the operating units on the same day or the following morning. The aim was to attempt to dust all contacts of every case on the day the case was reported. Each unit, equipped with a supply of powder and hand dust guns, visited the addresses assigned. Powder was applied in the usual manner to all persons as outlined above. If a unit had several addresses to visit, focal dusting was delayed until every patient and his household contacts were treated. Focal dusting was attempted later in the day or on the following day. In order to speed up the work of dusting the immediate family contacts, 2 dusters from the contact delousing section were assigned to work with each of the 8 case finding teams. These dusters were instructed to dust the cases and the immediate members of the family during the time of the first visit of the case finding team to the addresses in question.

The work of this department was essentially a room-by-room, house-to-house campaign in an attempt to effect a louse-free area around the place from which the case or cases originated.

SPECIAL SERVICES

The working units were made up in essentially the same manner as the units

of the case-contact service. In fact the teams of the two services were interchangeable and could be used for work of either.

Duties—The dusting teams were organized to do special project dusting of prisons, reformatories, religious institutions (if schools, then only the teaching personnel and not the school children were dusted unless typhus had been reported). Nuns and Sisters were instructed in dusting procedures and furnished some dust guns and a supply of powder, with the understanding that they were to train others and in this way accomplish the complete dusting of all the Sisters concerned. The priests were dusted in connection with the program of the immunization section. Homes for the Aged were treated on request. Carabineiri and civilian police were dusted in conjunction with the activities of the immunization section. Hospitals (general, special, mental), clinics, and sanatoria were included in the list of work for this service. Certain industrial organizations (upon request) and miscellaneous other groups of persons came under the activities of this service.

For smoothness of operation a priority list of dusting projects was established. The institutions in which cases of typhus had occurred were given highest priority. The remainder of the list was given priority based on the estimated urgency of the requests submitted to the field office of the Typhus Commission.

This service began operations with two units. The nurse in charge of each dusting team was given a work sheet on which were written the names of the institutions or groups of persons to be visited, addresses and map-reference zones. If a case of typhus had been reported, the patient's name was included on the sheet. Each team was then dispatched to the address or groups of addresses as indicated. Thorough dusting of all inmates, per-

sonnel and beds was accomplished. In some of the larger hospitals and prisons a routine dusting schedule at 14 day intervals was employed. In addition a daily application of powder was given to all new incoming prisoners brought in during the night. These prisoners were isolated in a separate wing of the prison and held until the dusting teams arrived on the following morning. Permanent dusting stations were set up by the mass delousing section to dust all incoming and outgoing patients, as well as any hospital visitors.

The special service teams worked in close coöperation with the flying squadron in assisting in carrying out a program of contact and focal dusting in nearby towns and villages. Assistance was also given to the work of the refugee section at the time of its organization.

THE RICOVERO SERVICE

This service was reorganized and placed in charge of the writer. The teams of this service were composed entirely of men:

1. Squad—An Italian civilian physician in charge, and 3 male dusters
2. Team—Two or three squads depending upon the amount of work to be done
3. Weapons' carrier and enlisted man as driver

The duties of the teams of this section were chiefly as follows:

1. Dusting of any cases, suspect cases, and corpses found in the shelters
2. Dusting of all persons, transient or permanent, living within these shelters. Dusting of beds and bedding in the shelters in which typhus had occurred or was present, or in cases where extreme lousiness was noted
3. Reporting of any new suspects or new typhus cases to the case finding section for investigation

Operation—The initial work of this service employed the services of six units. Each unit was composed of 3 squads of 4 men each. This number of

units remained the same during the period when case incidence was at its peak and for several weeks following. The number of squads was gradually reduced in proportion to the decreasing number of inhabitants found in the shelters as the epidemic died down and the fear of bombings decreased.

A list of 385 air-raid shelters comprised the work order for the teams of this service. The location of these shelters was marked on the map of the city and a list compiled of the names of these shelters grouped by map-reference zone. Each unit was given the responsibility for a certain number of these shelters in the zones assigned.

Work by necessity had to be done at night in order to be sure the majority of the inhabitants were "at home." An early curfew helped considerably in assuring the workers that the large majority of people frequenting these places would be found by the time the teams arrived. During the day the supervisor, in company with an Italian civilian employee, visited the shelters to be treated during the night. From this visit the amount of equipment and personnel necessary to complete the assignment were ascertained. In case the shelter was one of the larger ones, two units would be detailed to work this one shelter. A schedule was arranged so that each of the inhabited shelters could be visited once every 7 days. Approximately one-fourth of the shelters were inhabited more or less permanently at the time of the epidemic. Repeat check-up visits to many of the uninhabited shelters had to be made from time to time. All of the shelters in the city, as far as could be determined, were visited many times during the course of the work.

The dusting teams, as they entered the shelters, posted one or two men at each of the entrances—some *ricoveri* had as many as 4 separate entrances. These men were instructed to dust any

stragglers entering after curfew and to prevent anyone from leaving without having been dusted. The remainder of the team members proceeded to dust, one by one, the inhabitants of the shelters. Naturally there was plenty of excitement, but very little trouble was encountered among the people, and after a few visits, the teams were received with general good feeling.

Each person dusted was examined by the doctor in charge, in order to determine if a thorough dusting job had been done. Some were turned back for a repeat dusting. Counts of the number of persons treated were made by the leader of each squad.

During air-raids and air-raid alarms, hundreds of people would swarm into the shelters. Work was then nearly impossible. What effect the numerous air-raids may have had on a rise in the case incidence during the epidemic has not been determined.

MASS DELOUSING SECTION

The mass delousing section was the function of the Typhus Team of The Rockefeller Foundation under the direction of Dr. F. L. Soper, assisted by Drs. W. A. Davis, L. A. Riehl, and F. H. Markam. This section was organized primarily for the purpose of delousing the entire civilian population of the city of Naples.

In order to carry out such a massive program, powdering stations located at strategic points throughout the city were established. Plans were formulated for the installation of 50 such delousing stations equipped to dust as many as 100,000 persons per day. These stations were located in churches, schools, railway stations, hospitals, quarantine stations on roads leading out of the city, and empty buildings. The sites were chosen based on density of population, rate of typhus in the immediate neighborhood, and convenience to homes, factories, and shops.

Each station was in charge of one person who served as foreman. He was directly responsible for the teams under him, which numbered from 4 to 24 persons depending upon the location and size of the station. The work of the stations was supervised by several Italian civilian doctors each of whom was responsible for from four to eight stations.

By January 3, 1944, 10 dusting stations had been established. This number was gradually increased to a total of 40 operating stations by February 8 in which 439 persons were employed. As the severity of the epidemic diminished the number of stations and personnel was gradually reduced.

This section, as the number of typhus cases diminished, turned a share of its attention to a survey of the various zones of the city to determine as nearly as possible the percentage of persons in the city who had been dusted one or more times, and the extent of lousiness still present. In zones where less than 70 per cent of the population reported having been dusted but one time, special house-to-house dusting, using the block as a unit, was organized on February 6. A similar system was in use by the contact delousing section about the same time. On February 14 the block dusting operations of the two sections were coördinated, and placed under the supervision of Drs. Markam and Riehl of the mass delousing section.

THE IMMUNIZATION SECTION

This section was organized by Captain (now Major) R. S. Ecke, M.C. (AUS), and Major R. L. Rogers, M.C. (AUS). Although an important section, its function was entirely apart from the DDT control program and will be discussed in a future more detailed report.

THE FLYING SQUADRON SECTION

In order to cope with the cases ap-

pearing in outlying districts the necessity for a completely mobile, self-contained case finding, immunizing and delousing service was apparent. Such a service was organized and directed by Captain (now Major) T. E. Woodward, M.C. (AUS), a member of the Typhus Commission.

Organization—The flying squadron was organized January 7 to conduct typhus control measures among civilians in towns and villages of Southern Italy.

The original plans submitted to the Field Director of the Typhus Commission called for an investigating team composed of a physician, an interpreter, and a driver. The purpose of this team was to investigate all suspects reported from areas outside Naples proper, diagnose the case, if possible, and, regardless of whether or not the patient was a definite typhus case, the team performed the following work:

1. Powdered all the family members present and the beds, bedding and extra clothing
2. Powdered other persons in the house or building who might have been close contacts
3. Vaccinated the immediate family and certain other possible contacts, using the one-dose method
4. Summoned the ambulance for isolation of the patient

While in the town the team consulted the responsible military and civilian authorities concerning future installation of mass powdering stations if conditions demanded. In areas near Naples these stations were to be organized and the work conducted by the mass delousing section, otherwise the personnel of the flying squadron would operate a temporary mass delousing station. Arrangements were also made for large-scale vaccination of hospital personnel, nurses, doctors, and certain organized civilian groups if necessary.

Up to April 1, 1944, 43 towns were visited by the teams of the flying squadron, including one trip by Major Woodward via plane, to Lecce, a town

TABLE 1

	Cases	Number of Dustings				Total
		Contacts	Special Service	Ricoveri	Station	
Naples	1,404	270,315	56,725	112,294	2,214,122	2,653,456
Outside Naples	510	201,257	411,073	612,330
Total	1,914	471,572	56,725	112,294	2,625,195	3,265,786

(Data in the above table furnished by Dr. F. H. Markam, International Health Commission of the International Health Division, Rockefeller Foundation.)

in the "heel" of Italy. In these towns 257 cases of typhus had occurred and contacts of these cases were dusted. By September, 1944, 510 cases in 68 towns and villages in Southern Italy had occurred.

THE REFUGEE SECTION

As the war progressed the refugee problem became more and more acute. From Yugoslavia refugees came into Italy from across the Adriatic Sea and landed in scattered places along the eastern coast. Attempts by certain agencies were made to collect these refugees and bring them into one central point. At this point attempts were made to collect these people and disinfect them before transferring them to Taranto for subsequent shipment to refugee camps in Syria, Egypt, Palestine, and North Africa.

The original plans of the Typhus Commission provided for the organization of a section to deal with such conditions. Major R. S. Ecke, M.C., was instructed to organize the work on January 27, 1944.

Through the efforts of Major Ecke and under his supervision, facilities for delousing refugees and their effects were provided at all of the refugee collecting points in Southern Italy.

By January 10, 1944, within a month after control operations had been put into effect, the peak of the epidemic had been reached and a sharp decrease in the number of reported cases occurred. By February 20, 1944, the

typhus fever epidemic in Naples appeared to have been definitely broken and, upon direction of Brigadier General L. A. Fox, the majority of the U. S. Typhus Commission members were called back to their headquarters in Cairo. Major Woodward and Major Ecke remained for a few weeks longer working with their respective sections in dealing with typhus outside Naples and with the refugee problem. Responsibility for further control operations was placed in charge of the Allied Control Commission under the direction of Lt. Col. W. C. Williams, M.C. (AUS).

The combined efforts of the sections responsible for the application of the lousicidal powder to the clothing and bedding of typhus patients and their household contacts apparently played the important rôle in arresting the typhus epidemic in Naples and Southern Italy. Mass delousing reduced the louse population density to a low level, and the contact delousing operations eliminated the great percentage of infective lice.

Table 1 summarizes the total number of reported cases together with the total dusting figures of all sections concerned.

At the time of writing this report, 9 delousing stations are still in operation in Naples, which handle an average of 500 persons daily who come in voluntarily to be dusted. At various localities in Southern Italy, supplies of 10 per cent DDT powder and dust guns are furnished to responsible health authori-

ties in order to take care of any local outbreaks that may occur.

In future operations the importance of case finding and contact delousing cannot be over-emphasized. These two sections must work in close coöperation at all times.

Availability of supplies, complete organization of the control program,

intensive and extensive case finding, immediate isolation (hospitalization) of cases, rapid but thorough contact delousing of immediate family contacts, and sufficient and dependable transportation are cardinal points in the successful execution of a typhus control program based on the use of a lousicidal powder such as DDT.

Citizen's Planning Committee for Coördination of Voluntary Health Agencies

The Gunn-Platt report, *Voluntary Health Agencies — An Interpretive Study*, continues to make history. In response to requests from local citizen groups all over the country, the National Health Council has organized a Citizen's Planning Committee. This committee of 25 citizen-leaders in many fields of public service will furnish the leadership for a movement to coördinate the work of the 20,000 voluntary health agencies of the country. In the words of the authors, this is the outstanding need of the voluntary health field of today. "If we are to avoid authoritarian prescriptions or regimentations, we must direct our efforts toward a unified health purpose in the broadest terms, and we must build up this essential unity in service by deliberately federating the independent specialized organization from the ground up."

This committee met in New York on January 16, and organized its work for the coming year. Full details will be reported in a later issue of the *Journal*.

The members of the committee are:

Leroy A. Lincoln, Pres., Metropolitan Life Insurance Co.

Raymond B. Fosdick, Pres., Rockefeller Foundation

Chester I. Barnard, Pres., New Jersey Bell Telephone Co.

Guy Emerson, Vice-Pres., Bankers Trust Co.

Louis I. Dublin, Ph.D., 2nd Vice-Pres. and Statistician of the Metropolitan Life Insurance Co.

Irving Abramson, Chairman, C.I.O. Community Services Committee

Mason Bigelow, President, National Society for the Prevention of Blindness

Morgan B. Brainard, Sr., President, Aetna Life Insurance Company

Senator Thomas C. Desmond of New York

Charles T. Fisher, Jr., President, National Bank of Detroit

Ralph Hayes, Executive Director, New York Community Trust Company

Mrs. Shepard Krech, President, Maternity Center Association

Mrs. Albert Lasker, Secretary, National Committee for Mental Hygiene

Mrs. Oswald B. Lord, National War Fund

Mrs. William Barclay Parsons, former Administrator, Volunteer Special Services, American Red Cross

E. A. Roberts, President, Fidelity Mutual Life Insurance Company

Col. Howard A. Rusk, *New York Times*

A. J. Seymour, General Manager, National War Fund

Tom K. Smith, President, Boatmen's National Bank of St. Louis

Arthur Hays Sulzberger, President, *New York Times*

Gerard Swope, General Electric Company

Ray Lyman Wilbur, M.D., Chancellor, Leland Stanford University

Mathew Woll, 2nd Vice President, American Federation of Labor

Immunological Studies on an Epidemic of Influenza in Iceland

BJÖRN SIGURDSSON, M.D., AND ÓLAFUR BJARNASON, M.D.

Department of Pathology, University of Iceland, Reykjavik

IN the fall of 1943 an epidemic of influenza occurred in Iceland. In Reykjavik the first cases were reported on the 12th of October and the epidemic lasted about 5 weeks.

The disease was comparatively mild and presented the usual clinical signs—fever, headache, respiratory symptoms, etc. It is well known that an epidemic of influenza occurred in England and America at about the same time.

Figure 1 is based on statistics from Dr. M. Pétursson the Chief Health Officer for the City of Reykjavik and shows the number of reported cases of

influenza during the course of the epidemic.

From these data it will be seen that the epidemic reached its highest point quickly. It should be pointed out, however, that in the week preceding the peak of the epidemic, although only 6 cases of influenza were reported, an unusual number of cases of "catarrhus respiratorius acutus" occurred. Probably several of the first influenza cases were erroneously given this diagnosis.

MATERIALS AND METHODS

It was desired to find out what type

FIGURE 1

of virus had been responsible for this outbreak. An attempt was made to detect virus in nasal washings and garglings from 4 patients in the acute stage of illness. As a sufficient number of ferrets were not available, inoculations into chick embryos only could be carried out.

The nasal washings were filtered through Gradocol membranes and inoculated into eggs. The amniotic fluid was harvested 2 days later and passed into other embryos. Four such passages were carried out with each inoculum. Each time the fluids were tested for agglutinins against chicken erythrocytes by Hirst's method. No agglutinins were found and the attempts to isolate virus were thus unsuccessful.

Facilities were not available to carry out more extensive attempts to isolate virus as would have been desirable. This report is concerned with the detection of a rise in serum antibody titer against one or other of the influenza virus strains.

Samples of blood were taken from 22 patients on the first, second, or third day of illness. Second samples were obtained from 18 of these patients 3-4 weeks later.

The two samples of serum from each of these 18 patients were subsequently tested for antibodies against 3 strains of influenza virus, i.e., A, B, and swine virus.

The technic employed was that de-

scribed by Hirst, utilizing the power of specific antibodies to inhibit the agglutinating effect of the virus.¹

STRAINS OF VIRUS

The A virus was the PR8 strain, the B virus the Lee Strain, both of them brought here by one of us from the Rockefeller Institute in Princeton, N. J., U. S. A. The swine strain was kindly sent to us by Dr. C. H. Andrewes, The National Institute for Medical Research, London.

The viruses were maintained by intraembryonic inoculations in chick embryos, incubated at 37° C. for 2 days and the embryonic fluids then harvested.

In order to control the identity of the strains of virus, they were tested against known specific immune sera, using the red cell agglutination as indicator reaction.

The sera against A and B viruses were ferret sera obtained from Dr. G. K. Hirst of the International Health Division of the Rockefeller Foundation, New York, and the anti-swine virus serum was swine serum obtained from Dr. R. E. Shope of the Rockefeller Institute in Princeton.

The results of such tests are shown in Table 1. It seems beyond doubt that the virus strains were correctly labeled.

The technic employed in the main test was that described by Hirst.¹ The sera to be tested were diluted in two-fold steps in saline. The lowest dilu-

TABLE 1

Control of the Identity of the Viruses Employed. The Inhibiting Effect of Known Specific Antisera on the Agglutinating Power of the 3 Virus Strains

Virus Strain		Dilution of Serum								
		1/20	1/40	1/80	1/160	1/320	1/640	1/1,280	1/2,560	1/5,120
PR8	{PR8	0	0	0	0	0	0	0	0	+
	{Lee	+	+	++	+++	++++	++++	++++	++++	++++
	{Swine	++	++	+++	++++	++++	++++	++++	++++	++++
Lee	{PR8	+	+	++	+++	++++	++++	++++	++++	++++
	{Lee	0	0	0	0	0	0	0	0	+
	{Swine	++	+++	++++	++++	++++	++++	++++	++++	++++
Swine	{PR8	0	+	++	+++	++++	++++	++++	++++	++++
	{Lee	+	++	+++	++++	++++	++++	++++	++++	++++
	{Swine	0	0	0	0	0	+	++++	++++	++++

tion of serum used was 1:8 in terms of final concentration after the red cell suspension had been added. The amount of virus put in each tube was four times the quantity needed to cause a ++ agglutination in the absence of inhibiting serum.

The results are shown in Table 2.

Significantly higher titers in the second or convalescent serum samples, as compared with the first of "acute" samples from the same patients, were found against the PR8 strain and the swine virus. In ten cases a fourfold increase or more was observed against the PR8 strain and in 11 cases a similar significant rise in titer against the swine virus was observed.

Eight sera showed a significant rise against both A and swine virus, 5 sera against only one of them, and in another 5 sera no significant rise in titer against any of the strains was detected.

No significant rise in titer against the B strain was found.

DISCUSSION

The influenza epidemic that occurred in England and America in the fall

of 1943 has been rather intensively studied.²⁻⁶

It seems to be generally agreed that A strains of influenza virus were predominant, as virus was isolated on numerous occasions and found to have the characteristics of the A strains, and a rise in antibody titer was observed against A virus but not against B strains.

No reports of titrations of antibody against swine virus in sera from this epidemic have come to our notice.

In our material a rise in titer that must be considered significant occurred against both the A strain and the swine virus. It seems to be established beyond doubt that the viruses were correctly labeled. The entire series of sera were titrated twice against both the PR8 and swine viruses with practically identical results.

Three possible explanations suggest themselves. The first is that a strain immunologically related to both the swine and the PR8 strain employed was responsible for the epidemic. Unfortunately no virus was isolated from the

15	1/16	1/32	1/512	1/256	1/128	1/1,024
17	1/64	1/512	1/512	1/512	1/1,024	1/2,048
18	1/16	1/128	1/128	1/128	1/256	1/1,024
19	1/128	1/128	1/256	1/256	1/128	1/128
20	1/32	1/128	1/256	1/256	1/256	1/2,048
21	1/32	1/512	1/128	1/256	1/32	1/128
22	1/32	1/64	1/256	1/256	1/256	1/256

Figure 1 shows the number of reported cases of influenza and of "catarrh. resp. ac." during the epidemic in Reykjavik

epidemic in Iceland so this possibility cannot be directly tested experimentally.

Horsefall and Rickard⁹ and others have reported a significant rise in titer against swine virus in epidemics of virus A influenza. It has been suggested that an antigenic relationship is responsible for such rises in titer against the swine virus. Recently swine influenza virus strains have been isolated in Great Britain that seem to be antigenically related to the influenza A (PR8) virus.^{7, 8} These findings indicate that strains exist which combine in their antigenic make-up properties of both A strains and swine virus.

In our material a significant rise in titer against one virus only occurred in 5 instances: 3 times against the swine virus and twice against the A strain. This fact may seem to contradict the idea that one single strain of virus was responsible for the outbreak, but might be explained as follows: It is well known that in an epidemic of influenza a considerable percentage of cases of clinical influenza may fail to show a rise in antibody titer to the responsible virus strain.

In two cases that have come to our notice, influenza virus has been isolated from patients who did not show a rise in antibody titer during the course of their illness.^{5, 10} From the work on the antigenic relationship of influenza virus strains we have to assume that a given strain contains several different antigenic components, probably in different proportions, but some of them in common with other related strains.

Let us call some of these antigens in a given virus particle X, Y, etc. It is known, as previously mentioned, that influenza virus may fail to elicit any productions of antibody in case of influenza. It is reasonable to expect that in other cases a response to antigen X only is provoked or to antigen Y only. If antigen X represents the relationship

of the given strain to the A virus for instance, a case with high antibody to antigen X would be classified as a probable case of A virus infection. If antigen Y represents the relationship with swine virus, a case with high antibody to Y antigen would be considered suspect for swine virus infection, especially if the response to antigen X at the same time were weak.

It is even possible that an infection with strain A may provoke a response to antigen Y only, and thus mimic a swine virus infection.

Similar explanations have already been offered by Bodily and Eaton¹¹ to account for immunological cross-reactions encountered in their studies on different strains of influenza virus.

The second possibility is that two strains of virus were prevalent in this epidemic, one of them related to or identical with the A strains and the other related to or identical with the swine virus. It might then be assumed that they sometimes occurred together in the same individual, as 8 of our cases showed a significant rise in titer to both A and swine viruses.

An explanation along similar lines was made by Hammon and Howitt^{12, 13} with regard to western equine encephalomyelitis virus and St. Louis encephalitis virus, in outbreaks of encephalitis. They suggested that the two viruses were responsible for epidemics of encephalitis that occurred in the Yakima Valley in the summer of 1940 and in the Yakima Valley and in Arizona in 1941. Their evidence suggests the possibility that both WEE virus and St. Louis virus may be present in the same epidemic and even in the same patient, as they found in two of their cases a rise in antibody titer, that they considered significant, to both viruses.

The third possible explanation is that the rise in titer to one of the viruses is "anamnestic," or that the infection with one of the strains furnished nonspecific

stimulus to the renewed production of antibody to the other strain. It would then have to be further assumed that the persons in question had recently gone through an infection with the other strain.

This possibility however, should, we believe, be entirely disregarded for several reasons. The main reason is that the rise in titer is fairly high and is about equal for both viruses. The general experience with viruses seems to be that any considerable rise in antibody titer occurs only during actual infection with the virus, or related viruses, or after immunization.

It seems to us that, before the second or third explanation could be accepted, very strong direct evidence for their validity should be forthcoming, although the occurrence of mixed epidemics is a very interesting possibility that should be kept in mind.

SUMMARY

An epidemic of influenza occurred in Iceland in October and November of 1943. Attempts to isolate virus by inoculations in chick embryos were unsuccessful.

Using Hirst's agglutination technic, a significant rise in antibody titer against A strain and a swine virus strain was found in the sera of a majority of 18

cases studied. No rise in antibody titer against a B strain (Lee) was found. The possible significance of these findings is discussed.

Resolutions Enacted by the United States Conference of Mayors

Among the resolutions adopted by the United States Conference of Mayors in annual conference, December 10-12 were the endorsement of the general objectives of the General Housing Bill of 1945 (S. 1592); the petitioning of Congress to enact legislation providing for 100,000 temporary family housing units and urging that such temporary housing units be operated and ad-

ministered by city housing authorities or other appropriate agencies of municipal government; the petitioning of Congress to extend the expiration date of the Emergency Rent Control Act until the present housing shortage is corrected; and urging the adoption of a program of federal aid to municipalities for hospital construction, expansion, and modernization.

Public Health Field Experience

BENJAMIN G. HORNING, M.D., F.A.P.H.A.

Field Director, W. K. Kellogg Foundation, Battle Creek, Mich.

THERE is general agreement among persons concerned with the education of public health personnel that their preparation should include a period of field experience as well as academic training. There are a number of schools which provide good academic training, including the 9 schools of public health and the 31 schools which offer accredited programs of study in public health nursing. In contrast with the fairly extensive academic resources, satisfactory field training facilities for public health personnel and professional students are extremely limited.

For the purpose of this discussion, field experience will be divided into three types. The first is provided concurrently with and is coördinated with the academic courses of the professional school. This experience may be through observation, limited program participation, or a combination of both. It provides the student with an opportunity to observe and to make prompt practical application of information gained through classroom work. The area used serves as a field laboratory for faculty and students, and should be located near the school. The second type of field experience consists of periods of observation and orientation planned for visitors, students, or newly employed personnel. Recipients of this type usually do not participate in the program. It would seem advisable for each state to have facilities with which to provide this experience. The third type of training is supervised field work. This paper is concerned for the most

part with this kind of experience.

"Supervised field work for public health students" is a phrase used to describe a learning experience planned for students whereby they become supplementary health department staff members, assume responsibility, and participate in the program, but work under supervision. Students are assigned to the agency by the professional school for a specified period of time. It is comparable to the internship required for medical graduates. Such experience is a requirement of the 31 professional schools which provide accredited programs of study in public health nursing and of one school of public health for health education students preparing for the Master of Public Health degree. Other schools preparing public health personnel usually advise such experience although it is not as yet a degree requirement. In a few areas attempts have been made to provide supervised field work concurrently with the academic courses. This is generally not practical, because the field training facilities adjacent to the school can supply satisfactory experience for only a small number of students and because it is difficult for the official agency to assign real responsibility to students working on a part-time basis. For these and other reasons to be discussed it is believed that field work concurrent with academic work should be provided but that it should not take the place of the "block of full time" or internship type of supervised field experience.

MICHIGAN COMMUNITY HEALTH PROJECT FIELD TRAINING CENTER *

The Michigan Community Health Project, initiated in 1930, is a coöperative undertaking of the W. K. Kellogg Foundation with state and local agencies, and the people of seven counties in southwestern Michigan. During the early years of the project, many types of continuing education courses and workshops were provided; one of the objectives of these was to develop professional and lay leadership and to motivate persons to study and to take part in the solution of their own problems. Frequently such educational procedures were carried on in coöperation with professional schools and universities. As the various programs were developed, such schools encouraged selected graduate students to visit the area in order that they might observe and take part in the various community activities. The number of students seeking such experience increased rapidly and it soon became evident that there was a real need for field training

W. K. Kellogg Foundation took the initiative in developing a field training center for public health personnel and students in the seven counties of the Michigan Community Health Project.

The development of the present programs of the Field Training Center has been an evolutionary process. The experience with students during the early years served as a basis for establishing administrative patterns and standards, and for developing learning experiences to meet the individual needs of professional students. By 1937, programs had been developed for public health administrators, public health nurses, and public health engineers. Since that time field experiences have been arranged for dentists, health educators, hospital administrators, and veterinarians. For the nine fiscal years ending August 31, 1945, a total of 445 public health students have had 8,002 weeks of supervised field work, or an average of 18 weeks each. The number of weeks by type of professional student will be found in Table 1.

centers where professional schools could send their students to apply under supervision the theoretical knowledge which they had acquired during the academic years. This need was especially great in the field of public health, and after due consideration the

In addition to supervised field work, observation and orientation experiences were provided for large numbers of students, newly employed public health personnel, and distinguished visitors from the United States and abroad during this period. The total student weeks of all types of experience provided for the fiscal year ending August 31, 1945, will be found in Table 2. It

Hospital Administrators	1	5	40	17	41	22
Total	76	786	202	208	278	994

will be noted that 278 persons were provided with 994 weeks of training. Of the total student weeks, 786 were of supervised field work and 208 were of observation and orientation experience.

The Field Training Center in this area is now a joint undertaking of the seven local health departments, Michigan Department of Health, the professional schools using the area, and the W. K. Kellogg Foundation. Representatives of these agencies plan the activities jointly. Programs are flexible, and the experience of each student is individualized on the basis of past experience, education, and needs. The student who comes into the area for supervised field work becomes a supplementary health department staff member. After a short period of health department and community orientation, he takes an active part in the program. At first his work is closely supervised, but as he becomes more experienced he requires less direct supervision and participates actively in the service program. The primary objective for the student is a good educational experience. To achieve this the agency staff and student must of necessity provide a high quality of community service.

The W. K. Kellogg Foundation thus far has assumed full financial responsibility for the teaching program of the field training center of the Michigan Community Health Project area. Now that such training has been recognized

as an essential part of the preparation of public health personnel, it is hoped that funds with which to provide field experience will be available from official sources. In this area the cost of field training is being determined. For example, it has been found that the weekly cost of supervised field work for public health nurses for periods not exceeding 12 weeks ranges from \$15 to \$25, depending upon the length of the experience, whether or not the field teacher supervises more than one student, and other factors. This figure does not include travel or living expenses of trainees. It should be pointed out, however, that after a short time the student begins to give independent service and usually becomes an asset to the program. Those students remaining for a period of more than 3 months require little more supervision than the average staff member. The most expensive field experience provided in this area is that of planned observation for foreign doctors of medicine. It averages \$80 per week.

The amount of funds necessary to administer the student program is estimated by the county director of health on the basis of personnel costs, student quotas, and other factors, and the W. K. Kellogg Foundation makes an annual grant directly to the county health department for this purpose. The W. K. Kellogg Foundation is also assisting a limited number of other states in extending their field training facilities.

In such states the grant is made to the state department of health to be allocated to the local field training area.

DISCUSSION

The extent of field training facilities in the United States is unknown at present and the total need has not been determined. An unpublished study* for the year 1941 revealed that a total of 533 public health students received supervised field work. This number utilized all of the desirable field training facilities available at that time. The professional schools in need of field training facilities for their students include the previously mentioned 9 schools of public health and the 31 schools providing accredited programs in public health nursing. In addition, schools of medicine, dentistry, basic nursing education, engineering, hospital administration, and veterinary medicine each year request field experience for selected students. For example, 27 schools of engineering have sent students to the Michigan Community Health Project field training center for supervised field work. With the increased number of public health personnel to be trained in the immediate post-war period, it is obvious that there is an insufficient number of field training facilities at present.

From the experience in Michigan and elsewhere it would seem that the place selected for a generalized field training program for inexperienced public health students should represent a typical cross-section of the area in which they expect to work. The first experience usually should be with an official agency. In the case of the nursing student it should provide an opportunity for her to make the transition from hospital to public health nursing through the use of her bedside skills. Unfortu-

nately this is not possible at present for the majority of students, because most official agencies have not yet accepted the responsibility for bedside nursing, and it becomes necessary for inexperienced nursing students to have their first experience with visiting nurse associations.

The health department staff should be adequate in number and preparation to care for both the service and the teaching programs. It has been demonstrated that in order to maintain a good service program in the average community there should be a minimum of (1) a qualified medical health officer, (2) one nurse of supervisory level for 5 to 10 staff nurses, (3) one staff nurse per 5,000 people, (4) one public health engineer per 25,000 persons, and (5) a health educator for units of 50,000 population or more and for units used as field training centers. For the larger population units additional medical personnel will be needed. Also one nurse per 5,000 population will not be sufficient if more than demonstration bedside nursing is planned. The experience in the Michigan Community Health Project area indicates that field teachers should be selected from the service staff on the basis of demonstrated teaching ability. The staff member will be able to give less service to the community while engaged in field teaching; therefore, the size of the staff should be increased sufficiently to compensate for the time given to the student program.

The staff members of a health department in an area used for a student program should be selected with care. They should be qualified by education and experience, and they should be mature, emotionally stable, and sensitive persons. It should be remembered that the health officer may administer an effective service program and yet be unsuccessful with a student program. Likewise, a public health nurse may

* McGavran, E. G. Preliminary Data on Rural Field Training Centers.

provide an excellent generalized service for her district but may not have the necessary qualifications for the guidance of students.

The basic program of the health department should be well planned and developed. For example, it would be unwise to assign a young student for generalized experience to an area with excellent venereal disease and tuberculosis control activities, but with a poorly planned maternal and child health program. Such areas are suitable for mature individuals with previous generalized experience, but not for inexperienced students. Just as a young doctor should have his internship in a hospital where good medicine is practised so should the first experience for public health personnel and students be in an area where good public health is practised.

Field training areas should be approved formally on a national basis by some professional body very much as hospitals are approved for internships. It would seem logical that this should be the responsibility of the national societies of the various professional personnel or the American Public Health Association. The basic service and student program standards and health department staff qualifications should meet with the approval of the professional schools and official health agencies.

There is general agreement among persons active in the training of public health personnel that all types of students should have supervised field experience, but there is a difference of opinion as to how long the period should be for certain types. In the Michigan area the requested periods for supervised field experience range from six weeks to one year. It would seem that when the teaching of public health has been properly and sufficiently integrated into the undergraduate professional curricula, public health personnel

should receive their supervised field experience as first-level staff members or internes with health departments which have been approved as field training areas. This is impossible now, however, because of lack of a sufficient number of such areas. The internship type of experience has the added advantage that students receive sufficient salary with which to pay for living expenses while receiving supervised field work.

The general supervision and coordination of field training areas should be the responsibility of the state department of health assisted by the local health department and the professional schools using the area. This assumes that there should be state department of health personnel qualified for such responsibilities. The field teaching program should be planned jointly by state and local health departments and the professional schools. It should meet national standards as well as those of the professional schools. The field training program should be administered by the staff of the local health unit. The responsibility for coordinating field and academic programs should be delegated to one or more persons who would ordinarily be on the staff of the state department of health. In the Michigan Community Health Project area such persons are on the staff of the W. K. Kellogg Foundation. However, all programs are discussed regularly with representatives of the Michigan Department of Health. The plan used for coordinating academic and field work is similar for all types of students. The program coordinators visit the schools using the area, become familiar with the academic curricula, meet the students, and review their past experience, education, and future needs. As the coordinators know the resources of the area, it is possible for them to assign the students to the county and the field teacher best suited for their

individual needs. The coördinators continue to serve as resource persons to health department staff members while the students are in the area. A faculty member of the school usually visits the area while the students are in residence.

At present requests for supervised field work in the field training center of the Michigan Community Health Project area are directed to the W. K. Kellogg Foundation by the professional schools using the area. The procedure followed in certain states is for the professional schools to make all requests to the state department of health coördinators who in coöperation with the staff of the local unit assign students according to their needs.

The citizens of the United States have a vested interest in public health personnel. The education of such personnel is expensive. Professional schools know the approximate cost of academic training, but there are very few data available concerning the cost of providing field experience. As previously mentioned, a careful study is being made in the Michigan Community Health Project area to determine the cost of such training for each type of student. The results will be reported in the future.

Since the main source of the budget for academic education in state supported schools is tax funds, it would seem reasonable that such funds should also be made available for field training. It must be remembered, however, that professional schools usually provide training for public health personnel

from several states, and that it would not be fair to ask the citizens from one state to finance field experience for personnel who are to be employed elsewhere. For this reason it would seem that federal funds should be provided to pay for the major part of the field training of public health personnel. The administrative procedure for the allocation of federal funds to the local level for public health purposes is already established. Federal funds are granted to states which in turn reallocate them to local health departments for specific purposes. This same plan could be used for the distribution of funds by the U. S. Public Health Service to help provide field training facilities in the various states.

SUMMARY

One of the major problems now facing persons and schools interested in the education of public health personnel is that of providing satisfactory field experience. It is urgent that a comprehensive study of the entire problem be made. Some of the questions to be answered are: (1) What are the present field training needs and resources for public health personnel and students in the United States? (2) What are desirable standards for field training areas and how should they be established? (3) Should field training areas be approved nationally and, if so, by whom? (4) How should field training areas be administered? (5) How much does it cost to provide field training? and (6) Who should pay for field experience?

Public Health Nursing Field Experience

MILDRED L. TUTTLE, R.N.

Nursing Director, W. K. Kellogg Foundation, Battle Creek, Mich.

AS has been indicated in a previous article,¹ seven county health departments² in southwest Michigan are being used by professional schools for supervised field practice in public health. During a two year period (1943-1945), a total of one hundred nurses had field experience in these agencies. The material for this article is based upon an analysis of the needs of this group of nurses.

At the present time there are 31 universities or colleges having a program of study for graduate nurses in public health, approved by the National Organization for Public Health Nursing. All students are required to have field experience in a public health agency as an integral part of this program. In 1943-1944 the following 173 agencies³ provided field experience to the students enrolled in the 31 approved programs of study in public health nursing:

County health departments....	112
Visiting nursing associations...	34
City health departments.....	14
Boards of education.....	8
Joint services.....	3
Teaching centers.....	2

On January 1, 1945, a total of 18,701⁴ nurses were employed by service agencies. This included 10,638 nurses employed by official health agencies, 4,321 by local boards of education, 4,742 by local nonofficial agencies.

The U. S. Bureau of the Census has recently given the population of our country as 140,000,000. On the basis of the present minimum standards of one nurse to 5,000 persons, there should

be 28,000 nurses in public health agencies. It is obvious that professional programs of study in public health nursing need to recruit many additional students. Increased enrollments will increase the need for field experience in public health agencies. The current expansion in prepayment insurance plans for medical care also offers another reason to anticipate a demand for more nurses for whom satisfactory field experience must be provided by the schools.

Study is needed to determine the ability of the 173 agencies now offering field practice to meet the anticipated demands both qualitatively and quantitatively. Although such a study was begun in 1943, war activities hampered its conclusion. The study should determine how nearly the student fields meet the usual standards for local health practice, and review the professional qualifications of the various members of the agency staff responsible for directing the educational program for students.

Further study of field agencies should determine how adequately they are meeting the standards and objectives of field experience as outlined by the professional schools. To date there has not been a country-wide job analysis of the usual positions for which public health nurses are being prepared. Such analysis, followed by a division of responsibility between the professional school and the field agencies, would help provide the objectives of field experience for the average student, with variations for particular schools, and

for individual students who could then proceed from a base line in orderly fashion. Analyses made at the same time for each member of the public health team—the health officer, nurse, engineer, health educator, and others—would be of even greater value in clarifying responsibilities and in outlining the objectives of field practice.

The professional schools and the field agencies selected by them for student practice must work as a team so that students will benefit from an integrated educational program of study. Teaching materials from the field agencies should be utilized more fully in the classroom so that principles and practices may be more closely related. The field agencies have a responsibility to the professional schools to provide the kinds of materials which will have value to the classroom instructor. A greater degree of continuity between the professional schools and field agencies is possible when there is a public health nurse-educator responsible for coördinating the program of the school and field. The coördinator brings together all of the factors involved in planning, executing, and evaluating field practice. The effective coördinator will know the content of the academic classes in the professional school, and she will know what each field agency has to offer to students. Until national standards are developed which can be used for accrediting field agencies for student field experience, the professional school must assume this responsibility.

The professional school should expect to find the following conditions present within the field agency:

1. A service program designed to meet the needs of the community according to accepted standards for local health service
2. Community interest, participation, and support
3. Qualified personnel
4. Educational opportunities for all staff members

5. Satisfactory personnel policies and practices

6. Democratic administration

7. Good staff relationships

8. Interest of the entire staff in the student program

The leadership and vision of the public health nursing supervisor in the field agency determine to a large extent the quality of experience which students will have. The supervisor should be well prepared in the basic areas of public health nursing, and it is desirable for her to have additional preparation on an advanced level. To avoid using all supervisory time in a student program and to make use of the great opportunity for developing the capacities of staff nurses, student advisement in public health nursing is frequently assigned to superior staff nurses. It is a fundamental requisite that the supervisor should be sensitive to the dual rôle of guiding the staff nurse in the service program of the agency and of helping her to translate the principles which she uses in working with individuals and families to comparable principles of guidance in working with students.

The selection and preparation of staff nurses for student advisement or guidance is a matter for serious consideration. It should be a prerequisite that the nurse selected to interpret public health nursing to students be an experienced worker, and have demonstrated an ability to work effectively on a professional level in the various areas of public health nursing. It is essential that she should have worked in a nursing district at least 6 months, preferably a year, to provide her with a thorough knowledge of the district and the families in the area. This knowledge is needed if she is to select the kinds of field experiences which will most adequately meet the individual needs of students. It is also essential that the nurse should be in the agency this length of time to enable the super-

vising nurse to work with her, to share field visits, and to utilize fully the conference method of guidance. The supervisor will appraise the effectiveness of the work and observe the methods used by the nurse in her contacts with individuals, families, and community. During this time the supervising nurse also has an opportunity to exemplify the quality of guidance which she expects the staff nurse to use when working with students. The preparation of student advisers should be carefully planned so that the nurse is introduced gradually to the responsibility of guiding students, first as an observer and later as an assistant. Through gradual introduction and planned preparation, the staff nurse develops a sense of security in working with students.

Before students begin their field experience, the coördinator visits the agency for the purpose of meeting with members of the staff who will be responsible for the students while they are in the field. The coördinator reviews the background of each student and makes tentative plans for her field experience on the basis of previous professional preparation, experience, interests, and needs. Upon arrival in the field agency, the student is introduced to an adviser who has been carefully selected for that particular student and who will be responsible for planning, interpreting, and evaluating the experiences of the student throughout her entire time in the field agency.

During the time students are with the agency, conferences for the evaluation of progress are held. Among those present are the coördinator, the supervising nurse, and the student advisers. The conference is based on the factual information contained in the adviser's cumulative record kept for each student and upon the narrative reports written by the students. The objectives for each student are reviewed in relation to

the experiences which she has had or which she still needs. These conferences provide an indirect opportunity to the coördinator and supervisor to appraise the effectiveness of the adviser's work with students. Each adviser will receive help from the coördinator and supervisor and from the other advisers in ways to improve her skills in selecting, guiding, interpreting, and analyzing the experiences planned for the student.

Student advisers who are good family teachers will find the conference method of guidance easily transferable to work with students. Sharing experiences in the field and discussing them afterward in conference is a stimulating experience for both the students and the advisers. Shared experiences may be visits to a home, school, library, social agency, physician's office, or a community meeting. Before the field visit is made, the adviser and student prepare for the experience by reviewing all pertinent information, agreeing on the objectives, and making tentative plans. Upon completion of the visit, the adviser and student analyze, evaluate, and record the visit.

The group conference in which a family situation is discussed is a guidance method which should be more generally used in field agencies. It is an educational opportunity for students to participate in the group conference in which a member of the agency staff presents a family situation for group analysis and study. Usually the nurse presenting the situation is seeking help from the group in making a more complete analysis of the needs within the family and the ways in which the nurse can be of greatest service.

Evaluation of the student's adaptability and growth should take place whenever the student and adviser discuss field experiences. The final conference should be a summarization of the entire experience and should emphasize the student's growth during the

time she has been in the field agency. Attention should be given, currently and on the conclusion of the experience, to the areas in which the student is weak and will need further help in order to render more adequate service to individuals, families, and community.

Study of the student program in the seven county health departments in southwestern Michigan has indicated the need to consider more carefully the type of field experience which will give added meaning and deeper insight into the opportunities for service in public health nursing. The seven counties follow the general objectives outlined by the professional school⁵ as a base line for planning field experiences for students:

Objectives—The specific objectives of field experience will vary according to the preparation, past experience, interest, and ability of the individual student. Careful selection of experiences is necessary if she is to have enough practice in applying public health theory to a practical situation to acquire any competence as a public health nurse. In general, it is more important for her to follow a few families, or projects than to have every type of experience.

In general, the student should gain from rural field experience:

1. An appreciation of the concept of family health work and increasing ability to give family health guidance.
 - a. Some ability in analyzing a family health situation, recognizing the resources and needs of the family, and seeing the relationship between health, economic, environmental, social, and psychological factors.
 - b. Awareness of the family as a unit, sensitivity to family relationships, and appreciation of the relationship between the family and the community.
 - c. Ability to plan and carry out a home visit.
 - d. Ability to record a family health visit.
 - e. Ability to evaluate her work with families and plan for improvement.
2. Ability to carry out procedures required of a public health nurse.
 - a. Skill in making home visits—approaching the individual and family, giving

the supervising nursing care in a rural situation as a representative of an official agency, and teaching health.

- b. Ability to establish good relationships and work coöperatively with other agencies and workers.
 - c. Ability to put principles of public health nursing into practice.
 - d. Ability to participate in the school program as a consultant.
 - e. Ability to participate in group discussion and possibly have some experience as a leader.
 - f. Skill in testing vision and hearing and in observing children; experience in assisting with clinics and with immunization, and other communicable disease programs, etc.
3. Some experience in studying a community and determining its health resources and needs.
 - a. Knowledge of sources from which pertinent information can be secured.
 - b. Ability to collect and interpret information about a community.
 4. Acquaintance with resources and organizations which are found in a rural community and an understanding of the nurse's relationship to them.
 - a. Acquaintance with rural health, social, economic, and occupational problems.
 - b. Understanding of farm life and rural attitudes.
 - c. Ability to work with limited facilities.
 - d. Ability to utilize established groups and work with volunteers and lay committees.
 - e. Understanding of the functions of state agencies and ability to work with them.
 - f. Appreciation of the problems of the rural physician, teacher, social worker, county agency, etc., and ability to co-operate with these workers.

(Visits to community agencies are usually limited to those in behalf of individuals or families with whom the student is working. General excursions are of doubtful value.)
 5. Some understanding of local government and the functions of public officials.
 6. Understanding of the place and functions of a local health department, its organization and support, and the responsibilities and relationships of the various personnel.
 - a. Understanding of the legal obligations and limitations of the health department.

- b. Understanding of the relationships of the health department to schools, private physicians, and dentists, and to county officials, and state agencies.
 - c. Understanding of the communicable disease program.
 - d. Ability to work effectively with all health department personnel.
7. Program planning.
- a. Ability to plan a program for a day, week, month, and year on the basis of health needs and available nursing time.
 - b. Ability to select cases and plan visits effectively.
 - c. Opportunity to observe and possibly participate in group work, classes, clinics, and school health programs.
8. Professional development.
- a. Opportunity for the student to determine her own qualifications for an interest in rural public health nursing.
 - b. Development of the student's ability to evaluate her own work.
 - c. An opportunity to experience constructive supervision and staff education.
 - d. Develop the student's ability to recognize her need for additional information and to use reference materials when necessary.
 - e. Appreciation of the need for continuous professional growth and the nurse's responsibility for her own education.
 - f. Develop good work habits and professional attitudes—promptness, ability to use time effectively, sense of professional responsibility.
- learning his responsibility for the organization and administration of the agency and its program.
 6. To have direct contact with the public health engineer and to visit with him in the field.
 7. To have direct contact with the health educator if there is such a worker in the agency.
 8. To work intensively with a few carefully selected families. Within these families opportunity will be provided for students to:
 - a. Give bedside nursing care.
 - b. Have additional experience in pediatrics with emphasis on normal growth and development.
 - c. Utilize the principles learned in parent education and family relationships.
 - d. Develop skills in interpretative recording.
 9. To have direct contact with community groups and to have experience in community organization.
 10. To plan, participate in, and evaluate group discussions.
 11. To see the place of the local librarian in a community program of health education and to work with the librarian on community education projects.
 12. To have direct contact with public health nursing consultants from the Michigan Department of Health and to utilize these resources in relation to specific field activities.
 13. To have experience in a field agency where staff relationships are built upon broad democratic principles.

The county health departments in southwestern Michigan which provide field experience are making additional contributions to the general objectives as set forth by the professional schools. Students will have an opportunity:

1. To see the entire agency in action and functioning as a unit.
2. To see the interrelationships of each working group within the agency.
3. To see the function of the agency in a community program and its responsibility for the overall planning to meet the total community health needs.
4. To have daily contacts with all members of the agency staff.
5. To have direct contact with the administrator of the agency for the purpose of

In making plans for the immediate future, the following questions need to be answered through further study of the existing practice fields:

1. To what extent will it be possible for the 173 agencies to provide field experience for more students?
2. Will it be necessary to develop additional field training centers, especially in rural areas? If so, where shall such centers be located?
3. To what extent is it feasible to consider internship in a qualified field agency which might replace the present arrangement for field experience?
4. What standards should be required of the agency before it is approved as a field teaching center?

5. How should field teaching agencies be accredited? and by whom?

6. Through what channels should the level of the present practices in field work be strengthened and improved?

Army Medical Forces of the European Theatre Prepare for the "Battle of the Winter"

From a strategy conference of United States medical officers in the European Theatre on November 16, 1945, word comes that "it is easily possible that the fate of more lives in Europe is at stake this winter than were lost due to the entire war." The conference was attended by nearly fifty American public health officers in the U. S. zones of occupation and the British zone of Germany, who are responsible for evaluating civilian health, and planning for public health programs and procedures so that disease and epidemics will not endanger the occupation forces or displaced persons.

Serious overcrowding presents the danger of epidemics of respiratory diseases. Hence "influenza watch stations" are being set up where cases and suspected cases will receive special laboratory and clinical study.

The shortage of experienced German public health personnel presents another problem. Denazification of the German health system has removed nearly 95 per cent of experienced public health officers, nearly 85 per cent of hospital personnel, and perhaps 50 per cent of doctors from private practice.

In October, diphtheria was the most prevalent among communicable diseases in the U. S. zone. Immunization of all preschool and school children up to the age of 12 has been instituted, as well as the improvement of diagnostic facilities and intensification of reporting, isolation, and treatment of cases.

During October, penicillin became

available for treatment of civilians with gonorrhea, which is second in order of prevalence. The supply of the drug will treat an estimated 225,000 cases. Its use is authorized only for the treatment of gonorrhea and its misuse severely punished. Other venereal disease control measures are: reporting of all cases, examination of all contacts and suspects, and treatment of all cases in civil venereal disease detention hospitals.

Scabies was the third most prevalent disease, due to lack of soap and personal hygiene facilities. It is hoped that supplies of benzyl benzoate will be available to supplant the usual German medications which are inferior in scabicial value.

Typhoid fever showed a slight decrease with improvement of sanitary control of water supplies, of sanitary facilities, and of food. Infectious dysentery has also been decreased by similar measures. Scarlet fever has been kept under control as has typhus fever, 8 cases of which were reported in October. DDT stockpiles have been delivered for disinfestation immediately when typhus is reported.

Among those attending the November conference were two Fellows of the Association, Major General Morrison C. Stayer of Carlisle, Pa., and Lt. Colonel W. A. Brumfield of Albany, N. Y., currently Chief and Venereal Disease Control Officer, respectively, of the Public Health Branch, Office of Military Government, U. S. Zone, Germany.

Restaurant Sanitation in the South Pacific

CAPTAIN KEITH D. LARSON, SN.C., AUS

South Pacific Base Command

THE controlling of sanitation in civilian eating establishments can be accomplished by one of two methods: either by police enforcement of set regulations or by the usually more desirable method of education and coöperation. In the United States, a town which allows its restaurants to be operated in an insanitary manner can be put off limits, but on small islands of the South Pacific this is nearly impossible. Here on the island of New Caledonia, Noumea is the only large city. It is built around the chief harbor, and consequently all traffic must go through the town. Besides this, the recreational value of the town is inestimable, for "going to town" offers considerable relief from the otherwise monotonous life in army camps. When in town, men naturally eat French cooking.

The fact that many soldiers and sailors were eating in civilian restaurants was very evident; therefore, the Island Surgeon was faced with the problem of how best to control the sanitation of civilian eating establishments. Two apparent methods presented themselves. It could be accomplished by inspecting each establishment and putting "Off limits" signs on eating places which were assumed to be dangerous. This would necessitate a large MP and SP force to enforce the off limits, and would result in many arrests. Besides being difficult to enforce, this procedure would antagonize the local government and

reduce to zero the coöperation between the civilian and military health services.

The other method would be to make inspections and approve those establishments which met or could meet the minimum sanitary standards by making certain changes. Taking everything into account, it was felt that the educational method would be the more desirable, and plans were made to carry it out. As a guide for the armed forces personnel and as an incentive for the

FIGURE 1—Approved sign being placed at the entrance of a Noumea restaurant. All "Approved signs" were posted in the presence of the restaurant operator by a military policeman under the supervision of the Island Sanitary Inspector and his interpreter.

improvement of sanitation, each establishment that was operating in a satisfactory manner would then be loaned a large white "Approved eating establishment" sign (see Figure 1).

This educational method of sanitation control seemed to be psychologically sound, and experience has shown that to be the case. Presumably, this method of sanitary control would accomplish the following:

1. Aid the French Health Service in enforcing their sanitary regulations.
2. Stop the soldiers from eating in insitary food establishments. (This has not been entirely accomplished but the number eating in unapproved places is very few and becoming fewer daily.)
3. Encourage the French to improve the sanitation of their restaurants on a voluntary basis.
4. Give teeth to an educational program in restaurant sanitation.
5. Make possible the enforcement of a few armed forces regulations.

During the latter part of August, 1944, work was started toward the carrying out of the approved eating establishment program for the restaurants on this island.

As a first step, all French laws regarding operation of restaurants were obtained and were mimeographed in both French and English to be given to the French eating establishment operators. (See appendix 1—French Regulations for Sidewalk Cafes, and appendix 2 — Regulating Hygienic Measures Assumed for the Preparation and Sale of Food.)

An examination of these French regulations reveals them to be very complete. The regulations adequately cover all requirements for the proper operation of any eating establishment. As a matter of fact, the Ordinance and Code Regulating Eating and Drinking Establishment, as issued by the U. S. Public Health Service, is not so exacting as the French regulations.

Therefore, the Surgeon assumed that only regulations pertaining to the serv-

ing and handling of certain foods were necessary. For this purpose a letter of regulations (see appendix 3) was drafted and copies in both French and English were given to each establishment which either was on the "Approved list" or was trying to qualify for approval.

It was announced to all eating establishment owners that the "Approved signs" would be given out on October 12, 1944. Thus every establishment was given sufficient time to make the necessary changes for compliance. At the same time that the owners were informed of the date, notices were issued to all commanding officers of army and navy units to instruct their personnel to eat after October 12, 1944, only in places that displayed the "Approved sign." Since the first of January daily radio broadcasts over the armed forces broadcasting station (AFRS) in Noumea have been given advising armed forces personnel to eat only in approved eating establishments. These radio broadcasts have been very effective.

Insanitary practices which were stressed during the "pre-approval" inspections were:

1. That general cleanliness of the kitchen, dining rooms, latrines, and yards be satisfactory.
2. That there be adequate storage facilities for bread, pastries, and meat. Some form of screened-in space had to be furnished for the storage of bread, pastries, and exposed foods. (Figure 2 shows a typical box.) It was not required that mechanical refrigeration be furnished; nevertheless, many did have modern refrigerators (see Figure 3). Each establishment was required to have either mechanical refrigerators or ice boxes.
3. That adequate dish washing facilities be furnished. At first the use of boiling rinse water as a sterilizing agent for the dishes was considered satisfactory, but subsequent inspections revealed that the rinse water in most establishments was never hot enough. Consequently, a chemical disinfectant was recommended. It was also recommended that the dishes be washed in the following manner: first washed in warm soapy water; then

FIGURE 2—The kitchen of a Noumea restaurant showing arrangement of stove, cooking utensils, and screened-in cabinet in right hand corner. Bread and pastries are stored in bottom part of cabinet and dishes in the upper part.

FIGURE 3—Interior of a Noumea restaurant showing modern refrigerator for storing perishable foods

FIGURE 4—Typical improvised method of dishwashing in a Noumea restaurant using hot soapy water, rinse and disinfecting solution

rinsed in clear tap water; and finally allowed to stand for from 4 to 5 minutes in a strong chlorine solution. This was made by using 1 level teaspoonful of Calcium Hypochlorite (70 per cent available chlorine) in 20 liters of water. Following this sterilizing rinse the dishes were air dried. (Figure 4 shows an improvised setup which we feel is satisfactory.) The U. S. Army made available through Lend Lease 1,250 pounds of calcium hypochlorite for sterilization of dishes in restaurants and glasses in bars. The calcium hypochlorite was packed in convenient 5 lb packages with removable, tight fitting lids, and the entire supply was turned over to the local French Health Department for issue.

4. That the kitchen be fly proofed by screening all outside openings. Since there was little screening available locally, and most of the screening had to be furnished on Lend Lease, the screening of the dining rooms though desirable was not recommended. In a few cases after operators saw the advantage of screening the kitchens they also screened their serving rooms by obtaining the screen from non-military sources. For this purpose the U. S. Army made available on Lend Lease 3,000 ft of good grade wire screen which was then distributed by the local health officer.

5. That the latrines be fly and rodent

proofed. In many cases, this necessitated the building of a new latrine. (Figure 5 is of a latrine built to comply with these recommendations.) Besides the fly and rodent proofing of the latrines, it was required that each latrine be furnished with seat covers and automatically closing doors. The city of Noumea does not have a domestic sewer system. Most of the human waste is collected in pail type latrines and disposed of by emptying into the bay near the city dump. A few eating establishments have modern flush closets which empty into septic tanks whose effluent runs directly into the storm sewers and street gutters.

6. That all food handlers have an up-to-date French Carte Medicale Professionnelle (French Health Office Food Handlers Certificate), and that they renew the certificate every 3 months after a physical examination at the Dispensaire d'Hygiene Sociale Institut Gaston Bourret (the French Health Office Laboratories). The local health office gives a very thorough food handler's examination, checking on intestinal parasites, and all contagious diseases with the exception of venereal diseases. When the general physical examination reveals that a food handler has a venereal disease the health certificate is not granted.

7. That the establishment complies with all

FIGURE 5—An example of a fly proof, sanitary pail type latrine which was constructed in compliance with recommendations for improving latrine facilities in order to qualify for the "Approved sign"

army regulations (see appendix 3). The French health officer asked that Regulation 1-b, "Serve no raw vegetables . . ." be changed to read, "Serve no raw vegetables except cucumbers and tomatoes." This request was considered by the Surgeon and he decided to allow the use of tomatoes and cucumbers if they were washed in boiling water and if the cucumbers were peeled. Those regulations which prohibited the serving of raw milk and inadequately refrigerated meat were enforced.

The results of this campaign have been very gratifying. It is impossible to list here all the things accomplished, but a few of the more apparent were:

1. The French health officers found that this program dovetailed with their educational program and gave their wholehearted cooperation. Dr. Tivollier, Le Medecin Commandant, Medecin du Bureau Municipal d'Hygiene, and representatives of the Surgeon meet weekly or oftener and discuss the program. On many occasions both the French and Army inspectors have gone on joint inspection trips. All recommendations, except those prohibiting the serving of

tomatoes and cucumbers, were enthusiastically supported by the local health officer.

2. The patronage in unapproved eating places was so reduced that eventually all establishments except one not receiving the approved sign went out of business.

3. The voluntary improvement of sanitation by the French was satisfactory. In August, 1944, there were 37 civilian eating places patronized by the armed forces. Of this group 24 received approved signs October 12, 1944; 5 did not receive approved signs; and 8 closed voluntarily rather than comply with the regulations. Of the 5 who did not receive signs, 2 received approved signs in November; 2 closed a few weeks later; and 1 is still operating with very small patronage.

4. The education program was effectively forced upon the shop keepers.

5. The enforcement of the armed forces regulations has been satisfactory. Two eating establishments had their "Approved signs" removed for a few days for infraction of certain French regulations. The managers of those establishments soon indicated that they wished to comply and to date have operated their restaurants satisfactorily. To give teeth to removal and return of the "Approved sign" all operators have been informed that no establishment will have a sign returned after the second removal.

The improvement of sanitation under the approved program of every restaurant and shop varied. Every restaurant showed some improvement; however, in order to indicate what was accomplished a rather thorough description of the changes of one establishment are given (see appendix 4).

SUMMARY

This paper describes the successful techniques of cooperation and education developed and used by the sanitary officers of a Surgeon's Section in the South Pacific. Though complicated by the different standards of a foreign culture, this sanitation program proved entirely workable throughout the period of the occupation of this island by the armed forces.

Appendix 1

FRENCH REGULATIONS FOR SIDEWALK CAFES

1. The floors, counters, and containers

should be washed thoroughly at least twice a day, using soap and hot water, walls washed daily.

2. The food handlers should have a quarterly examination by a competent physician (French).

3. If any of the help (food handlers) have any suspicious (contagious) infection or communicable disease they should be sent home, a doctor called, and the French authorities notified immediately.

4. They (food handlers) should wear clean clothes and their personal hygiene should be above question.

5. Only boiled water should be used in all their preparations.

6. Only powdered or evaporated milk should be used in chocolate drinks, ice cream, and any other preparation of food and drink.

7. The glasses, cups, saucers, or any other containers used for food be thoroughly washed first with boiling water and soap, then thoroughly rinsed with plain boiled water.

8. No food should be exposed; bread, cake and pies, etc., should be in an enclosed container or receptacle.

ARTICLE 677—3 JUNE 1941

Regulating hygienic measures assumed for the preparation and sale of foods (victuals).

The Governor of the free French in New Caledonia and dependencies, Office of Legion of Honor.

Having noted the decree of 12 December 1874 on the government of New Caledonia and dependencies.

Knowing the decree of 20 November 1911 carrying the application of the provisions of the law of 15 February 1902 relating to the protection of public health for New Caledonia and dependencies.

Having seen the regulations 764 of 7 October 1915 determining the measures of precaution to be taken for sale of foods preliminary cooking;

According to the proposition of the colonial council of Hygiene at its meeting on 9 May 1941;

The permanent executive committee of the council agreed on the following at its meeting on 3 June 1941.

RESOLUTION

The places of manufacture of foods,

bakeries, pastry shops, pork butcheries, restaurants will be regulated as follows:

The places of manufacture, handling and selling shall be spacious, abundantly aired, and enlightened by sun, and the floor will be covered with tile, brick or cement to allow washing.

(In cases of transition) Temporarily boards will be allowed in the old places. In no case will the floor be simple beaten earth. The roof shall always be in perfect condition.

These places do not necessarily have to have direct communications with dwellings and they will be removed at least ten meters from the closets.

The openings should be (supplied) covered and latticed with cloth.

The (implements) tools used in the manufacture should be kept in good condition and placed in state of propriety after every use.

The products used shall be shielded from all causes of pollution coming from markers, domestic animals, rodents or insects.

The water used in the manufacture should be furnished by canalization wherever potable water exists.

ART. 2—If the conditions of fitting out the shops and locations fixed by the preceding articles are not filled, the (exercising of the profession) permission to run the place will be withdrawn until the demandable improvements are made as per local order.

ART. 3—All the provisions destined to be eaten without preliminary cooking or washing on the part of the consumer should be kept from being soiled, especially by dust and flies by metal lattice work or cloth containers, exceptions being made in case of fruits that can be peeled or other foods that have an outside covering.

ART. 4—It is forbidden for the buyer to handle exposed foods that are to be eaten without preliminary cooking.

The foods to be eaten without cooking are comprised of bonbons, goodies, etc., and shall be served to the clients by the aid of palettes, wood or metal, with forks in hands.

The handlers shall during work wear a proper white blouse and cap.

This clothing shall not be worn except at work.

The food handlers can be forced to be examined themselves and to have a sputum examination at any time.

ART. 5—All the offenders of the preceding regulations will be punished by an imprisonment of 1 to 5 days and a fine of 1 to 15 Fr. or by one or the other of the two fines.

ART. 6—The regulation 764 of 7 October 1915 is rescinded.

ART. 7—The Secretary General, the Attor-

ney General, the Chief Judge, and the director of Public Health, are charged, each one according to his responsibility, for the execution of the present regulations.

Noumea, 3 June 1941.

SAUTOT

Appendix 3

U. S. PUBLIC HEALTH DEPARTMENT
OF NOUMEA
NOUMEA, NEW CALEDONIA

31 August 1944

To: Operators of Civilian Eating Establishments desiring to Sell to U. S. or N. Z. Armed Forces.

1. All operators of establishments wishing to sell or serve meals, lunches, food, or drinks to members of the U. S. Armed Forces or New Zealand Forces are required to observe the following rules:

a. Maintain their establishments in strict accordance with all French Sanitary Laws.

b. Serve no raw vegetables to United States or New Zealand personnel.

c. Serve no raw milk to United States or New Zealand personnel.

d. Serve to United States or New Zealand personnel only such ice cream as meets the U. S. Armed Forces sanitary standards for manufacture and handling of same.

e. Serve only such meat to United States or New Zealand personnel as has been kept under adequate refrigeration.

f. Permit inspection of their establishments, by United States or New Zealand Inspectors, at frequent intervals to determine whether or not the above provisions are being complied with.

2. An "approved" sign will be loaned to those operators whose establishments meet or exceed the minimum sanitary standards listed above, and who wish to serve meals, lunches, food or drink to members of the U. S. or N. Z. Armed Forces. "Approved" signs will be loaned to operators with the understanding that:

a. Signs will be placed in a prominent place on the premises.

b. "Approved" signs will be denied those establishments from which the signs have been recalled twice.

c. Operators of establishments wanting "Approved" signs will communicate with U. S. Public Health Department of Noumea.

d. "Approved" signs will be removed at any time, should an inspection show that the establishment is failing to meet the minimum sanitary standards.

W. S. DOUGLAS, Colonel, MC.

Director

Appendix 4

IMPROVEMENTS IN ONE RESTAURANT ACCOMPLISHED UNDER THE APPROVED RESTAURANT PROGRAM

As an example of what was accomplished we will select one of the restaurants which is now "Approved," and describe the conditions before instigating the approved program and the conditions as they are now. To be fair to the French, this restaurant was not typical of all restaurants, but was a good example of the more backward establishments. Some establishments had little to do other than screen the kitchen in order to comply with the recommendations for being approved.

On 23 Sept. 1944, a few weeks after the Poilu restaurant opened in the village of Païta, representatives of the Surgeon's Office made an official inspection and found conditions very unsatisfactory. At first it was felt that too many changes were needed in order to correct all the insanitary conditions noted, but the owner, M. Deplanque, asked us to make recommendations.

In the kitchen the following insanitary conditions were noted: hundreds of flies, many dirty empty food containers, a questionable dish, washing set-up, much exposed food. The entire room needed thorough cleaning and repairs.

In the dining room the floors were fairly clean but needed extensive repair work; the walls needed redecorating, and the tables needed a thorough renovation.

The back yard presented the most offensive conditions. The cement drainage ditches were clogged with decaying food, poultry were feeding on the back step, a small pig pen near the back door was breeding flies by the hundreds, the latrine was nothing more than a canvas screened-in area with a tin pail under an uncovered seat. The entire back of the seat was entirely open and allowed free ingress of poultry, rodents, and flies.

To increase further the possible health hazards of this restaurant, water was being served from a questionable source, and not all food handlers had food handlers' certificates.

The following general recommendations were made:

1. The complete screening of the kitchen, and furnishing the doors with automatic closing devices.

2. Thorough cleaning of the kitchen followed by painting and repairing of floors and walls.

3. The furnishing of adequate dish washing facilities. (See description of approved method.)

4. The furnishing of adequately screened-in food storage space.

5. The furnishing of adequate cold storage.

6. The renovation of the dining room by repairing floors, tables, and redecorating the walls.

7. The removal of the pig pen.

8. The construction of a new fly and rodent proof latrine.

9. The cleaning of all drainage ditches.

10. The elimination of poultry from the vicinity of the kitchen.

11. A thorough cleaning of the back yard.

12. The furnishing of chemically treated water for drinking and kitchen purposes.

13. The obtaining of food handlers' certificates for all personnel.

To comply with these recommendations in-

involved considerable labor and money. However, the owner, a former French soldier, seemed to be cognizant of the need for all these improvements and started to make them. During the following weeks, several reinspections were made of this establishment by armed forces inspectors who found the work progressing favorably. By 23 Dec. 1944, M. Deplanque had carried out all recommendations. He then had a clean, screened, adequately equipped, acceptable kitchen. The dining room was clean and redecorated. A new fly and rodent proof latrine was finished, the pigs were removed from the back yard, and the entire yard area was thoroughly cleaned. Every food handler had cards and actually showed signs of being proud to be a part of this reborn establishment.

AMERICAN PUBLIC HEALTH ASSOCIATION

Survey of the Blood Plasma Levels of Vitamin A, Carotene, Ascorbic Acid, and Tocopherols of Persons in an Area of Endemic Malnutrition

P. L. HARRIS, PH.D., K. C. D. HICKMAN, PH.D., J. L. JENSEN, PH.D., AND T. D. SPIES, M.D.

Research Laboratories, Distillation Products, Inc.; and Department of Internal Medicine, University of Cincinnati, Cincinnati, Ohio

THE problem of diagnosing sub-clinical vitamin deficiencies remains one of the most important on the agenda of the medical and nutritional scientist today. Early recognition and treatment of such deficiencies would be of untold value, especially in areas where nutritional lacks are endemic. If laboratory methods could be developed for the recognition of the deep-seated changes which are believed to occur during the beginning stages of deficiency diseases, most of the patients suffering from them would be spared years of ill health.

It was with this in mind that the research group in Rochester, N. Y., for the past five years conducted experiments to determine the concentration of certain vitamins in human blood plasma. The substances under most intensive study were vitamins A and E, but it soon became apparent that the concentration of carotene and vitamin C might follow the trends of the other two. Methods of measuring the four vitamins in a single sample of plasma

were perfected sufficiently for daily use and a survey was started on normal subjects in the Rochester area. Search was also made for a group of admittedly deficient subjects so that a comparison could be made between plasma contents of persons in fair and poor health.

Independently and for a long time previously, the University of Cincinnati has sponsored studies in nutrition at the Hillman Hospital, Birmingham, Ala., in an area where pellagra and beriberi have been endemic. These studies yielded valuable information concerning the diagnosis and treatment of specific nutritive failure.¹ Repeated analyses of dietaries, however, confirmed the consistent clinical impression that mixed deficiency states were of most common occurrence. Individuals sustained by dietaries deficient in many essential nutrients might show specific signs of deficiency of one or two or even three such nutrients. They might show the classical syndrome of pellagra, beriberi, or scurvy. Many such persons, however, showed no specific symptom or sign, but still were distinctly ill. Clinicians spoke of a "preclinical" deficiency state; a "biochemical" lesion. Little has been said or could be said about those individuals with more

Communication No. 69 from the Laboratories of Distillation Products, Inc.

University of Cincinnati Studies in Nutrition at the Hillman Hospital, Birmingham, Ala. These studies were aided by a grant from the Ingalls Foundation

generalized nutritive failure or of those whose illness was manifest by atypical signs.

The two groups of investigators, at Rochester and at Cincinnati, accordingly collaborated in an attempt to determine the vitamin status of admittedly deficient persons. In late 1943 a study was initiated and directed particularly toward determining the blood concentrations of ascorbic acid, vitamin A, carotene, and tocopherols in a group of patients of the clinic who seemed to eat an improper diet and had general and vague symptoms, but no diagnostic lesions uniformly recognized by physicians.

Of the patients who attended the Hillman Hospital Nutrition Clinic between March 15 and September 13, 1944, 350 were arbitrarily selected for the survey. Detailed records were available as to their symptoms, complaints, and diets for a considerable time prior to this study. Eight per cent of them were colored and most of the entire number were in a comparatively low income group.

Most of the "patients" presented the vague symptoms so often associated with B-complex deficiencies²: itching and burning of the eyes, photophobia, redness and thickening of the conjunctiva, burning of the tongue, nausea, diarrhea, headaches, insomnia, nervousness, tenderness of the muscles, numbness of the extremities, and loss of weight, sleep, and appetite. A few of these patients under observation have, and have had in the past, actual lesions of pellagra and riboflavin deficiency. The patients having these lesions were treated with synthetic niacin or riboflavin. After the lesions began to heal, the vitamins were discontinued but the patients still remained on their deficient diets. It should be emphasized, however, that none of the patients had acute lesions or were under treatment at the time the initial blood samples

were taken. In fact, the only lesions which might be said to be apparent at all were a few residual changes around the corners of the mouth and on the tongue and skin. There were 22 such persons in this group who had had, at some previous time, mild lesions but, since their symptomatology was in every way similar to the other persons in the "patient" group, they were arbitrarily included.

It was the laboratory practice to use the blood of a normal person along with each batch of determinations. There were 70 persons in this group of so-called "normals." Included were physicians, nurses, laboratory workers, and various professional men and women in Birmingham, all essentially healthy as indicated by negative clinical findings. The individuals tested, both "patients" and "normals," ranged in age from 6 to 80 years. Males constituted 40 per cent of the patients and about 60 per cent of the "normal" group.

The investigational procedure began with a clinical examination followed by a thorough questioning as to dietary habits and past medical and nutritional history. Dietary records were made by Jean Grant, nutritionist of the Clinic. Thirty ml. of venous blood were withdrawn and the blood plasma subjected to vitamin analyses.* Red cell counts and hemoglobin determinations were also made routinely. Differential counts were made whenever it seemed of interest.

The plasma of the venous blood samples was analyzed for vitamin A, carotene, ascorbic acid, and tocopherols. Vitamin A and carotene were determined by the method of Kimble³ and ascorbic acid by the method of Mindlin and Butler,⁴ using Bessey's⁵ correction

* Hugh Risley and William Swanson performed the vitamin analyses.

for turbidity, while the tocopherols were determined by a method of Quaife and Harris.⁶

No attempts were made to obtain fasting blood levels of vitamin A since Kimble³ found that ordinary meals do not cause a measurable increase in either vitamin A or carotene within 2 to 6 hours. The vitamin A levels are reported as micrograms, since pure vitamin A was used as a standard in constructing the calibration curve. The factor 3.50 may be used to convert micrograms of vitamin A to biological "units," assuming a value of 2,000 for converting E 1%, 1 cm.; 328 m μ to "units." As a matter of interest, if we wished to convert micrograms of vitamin A to the type units used by Kimble,³ we would multiply by the factor 2.54; to convert to the type units used by May⁷ and by Youmans,⁸ we would multiply by 0.39 and 3.33, respectively.

In order to minimize the effect of recent ascorbic acid intake on the blood level of this vitamin, a check was made to be sure that the patients had not eaten foods containing large amounts of ascorbic acid at the meal preceding the taking of the blood sample.

OBSERVATIONS AND DISCUSSION

The state of nutrition of the patients with respect to the vitamins tested for was found to be much inferior to that of the "normals" (see Table 1). The average vitamin A level of the patients was 72 per cent of that of the "normals," the carotene 70 per cent, the vitamin C 51 per cent and the vitamin E 75 per cent. Statistical calcula-

tions confirmed the fact that these differences were highly significant. However, in accordance with many unpublished clinical observations, it was found that persons on a very deficient diet may have high plasma levels of vitamins A, C, and E. This is an unexplained occurrence.

Vitamin A—Of our "patient" group, only 8 out of 350 were thought by any observers at all to show evidences of vitamin A deficiency, such as hyperkeratosis, thickening of the conjunctiva, etc., upon clinical examination. Five of these patients were colored.

Youman's, Patton and associates,⁹ in the portion of their report dealing with the vitamin A status of a large population, criticised each diagnostic criterion which they used (diet histories, dark adaptation measurements, clinical examination, and blood vitamin A level), but concluded in general that greatest reliance can be placed on the concentration of vitamin A in the blood. They state that a concentration below the generally established normal value may be taken as evidence of a deficiency. In this connection it is interesting to note that 90.8 per cent of our patient group had blood vitamin A values below the mean value of our "normal" group. Yarbrough and Dann¹⁰ also considered the level of vitamin A in blood as the most promising method of detecting mild vitamin A deficiency by means of a single test. In Table 2 the values are grouped quite arbitrarily according to so-called "deficient," "normal," and "well nourished" classifications. This bears out the fact that the "normals" are superior in

TABLE 1

Normal individuals had blood values between 51 and 71 micrograms %

Well nourished individuals had blood values above 71 micrograms %

vitamin A status to the "deficients."

Carotene—Few studies have been made regarding the variation of plasma carotene or its significance. Clausen and McCoord,¹¹ however, determined the plasma carotenoid level of a small group of supposedly normal persons over a period of one year and noticed a very definite seasonal trend depending on the intake of seasonal carotene-containing foods. From a minimal value of 154 $\mu\text{g.}\%$ in May, the average rose smoothly to a maximum of over 280 $\mu\text{g.}\%$ in September and then returned gradually to a minimum the following May. This is consistent with unpublished observations of Grant and Spies. Consequently, it is only when carotene levels of the test group can be compared simultaneously with those of a control group that plasma carotene measurements are significant. The evidence from our study indicated that the carotene status of individuals in the patient group was inferior to that of those in the "normal" group. Table 3, in which the subjects of both groups are arranged in an arbitrary classification, illustrates this fact quite clearly. This may have been due directly to a lower intake of food-carotene or indirectly to a poorer utilization.¹²

Vitamin C—In interpreting the significance of plasma concentrations of vitamin C, we are cognizant of the findings of Crandon, *et al.*¹³ that low, and even zero, values may not be

TABLE 3

Distribution of Subjects According to Blood Carotene Levels

	Deficient *	Normal *	Well Nourished *
"Patients" (% of total)	73	17	10
"Normals" (% of total)	27	45	28

* Deficient individuals had blood values below 175 micrograms %

Normal individuals had blood values between 175 and 250 micrograms %

Well nourished individuals had blood values above 250 micrograms %

critically dangerous unless maintained at such levels for several months. Nevertheless, we are in agreement with Keuther, Telford, and Roe¹⁴ in believing that important information with respect to vitamin C can be obtained by determining the concentration of ascorbic acid in the blood. As suspected, the concentration of ascorbic acid in the blood plasma of the patient group was significantly lower than that of the normals.

Youmans⁸ contends that plasma ascorbic acid values below 0.4 mg.% represent a definite state of deficiency in which physical signs of scurvy may appear. This may be interpreted to mean that the reserve supply of ascorbic acid is lowered to the danger point. Levels from 0.4 to 0.7 mg.% are borderline, still indicating hypovitaminosis. Values of ascorbic acid generally accepted as normal range above

TABLE 4

Distribution of Ascorbic Acid Blood Plasma (Classification according to Youmans⁸)

	Deficient *	Border-line *	Normal *	Well Nourished *
	%	%	%	%
"Patients"	61	16	16	7
"Normals"	13	23	40	24

* Deficient individuals had plasma values below 0.5 mg %

Borderline individuals had plasma values from 0.4 to 0.7 mg.%

Normal individuals had plasma values from 0.7 to 1.2 mg.%

Well nourished individuals had plasma values above 1.2 mg.%

0.7 mg.%, with those as high as 1.2 mg.% common in many well nourished patients. Individuals tested in the present study were classified in these groups as shown in Table 4. Only a negligible percentage of Birmingham patients can be considered well nourished, while a large percentage of them were in the subnormal classifications. The majority of the "normals" were concentrated in the two intermediate groups, although almost one-quarter had values above 1.2 mg.% of ascorbic acid which placed them in the "well nourished" classification.

Vitamin E—If an individual's blood level of tocopherol can be considered a measure of his status with respect to vitamin E, then the difference between the plasma levels of tocopherols for patients and "normals" can be considered of importance. It is our working hypothesis that in studies of this nature carried on over a period of several months, blood levels of the fat-soluble vitamins might reflect tissue stores of these factors. Consequently, if the storage of vitamin E in the muscle and liver is low as a result of subnormal intake or of inefficient utilization, then the blood levels eventually may also be low.

The average level of tocopherols in the blood plasma for the "normal" group in this study was 1.04 mg.%. Wechsler, *et al.*¹⁵ reported that 12 "normal" individuals under his observation had an average value of 0.95 mg.%. Similar results were obtained by Minot and Frank¹⁶ who found that the concentration of tocopherols in the blood of their 4 normal control children averaged 0.88 mg.%. Quaife and Harris⁶ found an average value of 1.2 mg.% in a group of 13 supposedly normal individuals. Accordingly, assuming that the range of values between 0.88 and 1.2 mg.% represents normal, values below 0.88 mg.% are subnormal and above 1.2 mg.% are well nourished

with respect to vitamin E, we can tabulate our results as shown in Table 5.

TABLE 5

Distribution of Tocopherol Blood Plasma Levels

	Deficient *	Normal *	Well Nourished *
Birmingham "Patients" (% of total)	67.3	26.2	6.5
Birmingham "Normals" (% of total)	31.4	40.0	28.6

* Deficient individuals had blood values below 0.88 mg.%

Normal individuals had blood values between 0.88 and 1.20 mg.%

Well nourished individuals had blood values above 1.20 mg.%

Obviously the "patient" group is inferior to the "normal" group in vitamin E nutriture.

SUMMARY AND CONCLUSIONS

A survey has been made of the distribution of vitamin A, carotene, ascorbic acid, and tocopherol concentrations in the blood of two groups of selected persons from the same locality—a group of 350 "patients" in the Nutrition Clinic and a group of 70 "normal" persons working in the same area. The "normal" persons had no symptoms, whereas the "clinic" patients all had symptoms but no diagnostic lesions.

The mean vitamin A, carotene, ascorbic acid, and tocopherol levels in the plasma of the patient group were significantly lower (72, 70, 51, and 75 per cent respectively) than those of the normals. These findings suggest that it would be worth while to administer vitamins A, C, and E, separately and under controlled conditions to determine the effect on the blood levels and whether or not there is an improvement in any of the symptoms. Such a test is now under way.

N. Y. Academy of Medicine Reviews President Truman's Health Message

The New York Academy of Medicine, on January 3, inaugurated George Baehr, M.D., who is Director of Clinical Research at Mt. Sinai Hospital, New York, and member of the New York State Public Health Council, as President. In his inaugural address Dr. Baehr presented a statement formulated by the Academy's Committee on Medicine and the Changing Order which is making a three year study, of which the final report will be published in 1946.

The Academy endorsed that part of the President's message relating to the construction of hospitals and related medical facilities, the expansion of public health and maternal and child health services, the advancement of support by the federal government of medical education and research, and the protection of workers against loss of wages resulting from sickness and disability. It did not approve an overall national compulsory scheme of medical

care. Instead it offered eight recommendations as follows:

1. That voluntary, non-profit insurance receive a thorough trial as a means of providing medical services for low-income families.

2. That in certain instances, and particularly when private resources are inadequate, government support be provided.

3. That careful experiments be conducted "at state and local levels with compulsory Government insurance, so that we may have in the near future comparative experience with the relative values of voluntary and compulsory procedure."

4. That better opportunities for continued medical education, whether graduate or post-graduate, be provided in order that requirements of newer medical services may be met.

5. That there be a gradual extension of group practice in close coöperation with high-grade hospitals.

6. That special emphasis be placed on preventive medicine in all forms of practice.

7. That basic public health services be provided for those communities that now lack them.

8. That provision be made for the education of the public in order that it may better know how to obtain treatment and coöperate in the prevention of disease.

Permanent Program for Typhus Fever Control in Memphis, Tennessee

JOEL C. BEALL

Public Health Engineer, Memphis and Shelby County Health Department

THE establishment of the rat control program in Memphis was due, not to the existing prevalence of rat-borne diseases, but to the realization that murine typhus is apparently spreading inland from the South Atlantic and Gulf Coast states. The program is therefore one of typhus prevention rather than control. Months of preparation, including education and administrative planning, were necessary before actual work could begin. Efforts were accelerated by the occurrence during August and September, 1943, of 6 cases of typhus (this was the total for the year) among employees in a local feed mill. It is a permanent program in the sense that permanent methods and materials are used and it has been established as a permanent activity of the Health Department.

The purpose of this paper is to present a description of events involved in the establishment of the program, and to tell of its operative methods and policies. Rat proofing, vent stoppage or rat stoppage, and rat eradication measures have been ably discussed in numerous papers and will not be dealt with in detail here except as they may relate especially to the successful prosecution of the program's objective.

ESTABLISHMENT OF PROGRAM

In November, 1943, the Typhus Control Unit of the U. S. Public Health Service assigned to the Health Department two of its field men, who remained

until the following June, lending assistance in establishing the program. Also in November, 1943, the City Commission adopted an ordinance requiring in part that:

1. All existing business buildings shall be rat proofed.
2. New construction of business buildings shall include rat proofing.
3. All business buildings shall be freed of rats and maintained in a rat proof and rat free condition.
4. Responsibility for rat proofing rests with owners and that occupants of business buildings are liable for rat eradication.

The ordinance further deals with rat harborage, storage of food and garbage, and places responsibility for enforcement on the Health Officer.

Realizing that enforcement of the ordinance involved the existence of an organization capable of carrying out rat control measures on a large scale, and believing that this was not available among the local pest control and construction firms, the Health Department established a permanent Typhus Control Service within its Division of Sanitation.

Since it was planned that the program, except for administration and inspection service, should be self-supporting without profit, the problem of financing resolved into one of providing a fund with which work could be started. The County Commission provided funds for this purpose and, although the amount was not limited, around \$8,000 was expended for stocks

of materials and equipment. This, in general, constitutes a revolving fund in that money collected for work performed is immediately converted into replacement supplies necessary for current and future operations.

Business blocks in the downtown shopping district were selected for the beginning of control work. This district was chosen for the dual purpose of giving protection against typhus fever to the greatest number of persons in the shortest period of time, and because of the greater publicity benefits which could be had by offering a demonstration of the work in the area most frequented by the city's population.

OPERATION OF PROGRAM

Field operations on a block by block basis began February 1, 1944, with one foreman and two common laborers forming a nucleus for field personnel. The program has as its present objective the elimination of rat life within business buildings. To attain this there are currently practised several interdependent phases:

1. *Surveys:*

Field surveys are designed to gather information which primarily is used to prepare estimates of rat control costs for presentation to building owners and occupants. For rat proofing, special field forms are provided on which items requiring attention are recorded, such as doors, ventilators, roofs, interior work, basements, etc. For each individual item the man hours and cost of materials necessary are estimated and recorded in the field. The estimator must know unit costs and must be capable of making rapid mental calculations. No recording is made of types or quantities of materials since they are furnished from a common stock available to all buildings where work is to be done.

Eradication cost estimates are based

on the assumption that it will require a maximum of 3 months for the elimination of rats within the average building. Attention must be given to the degree or quantity of rat infestation, size of the building, harborage, etc., in order to decide or estimate the portion of the trapper's work day which will probably be spent in the building for this period of 3 months. Knowing the trapper's wage rate, the estimator can readily compute the estimated cost of labor involved, to which is added a small figure for contingencies such as removal of rubbish and similar harborage and for poison bait. Although an empirical formula, this has shown very accurate results thus far. Experience of personnel assigned to making estimates is the prime factor in securing accuracy.

Estimates are purposely made high in order that the work may be performed for an actual cost slightly less than the estimate, thereby fostering the good will of the individuals who are paying the bill, and further giving a safety factor in favor of the Health Department.

2. *Presentation of Work Agreements:*

Following the survey and immediately preceding actual control work, building owners and occupants are personally contacted and presented with an official letter of notification of the rat control requirements and a work agreement on which is stated the estimated costs thereof. The letter, pursuant to the ordinance, advises that the building is not rat proof and contains an infestation of rats, and orders the inauguration or completion of work within a certain time. Should an individual choose to disregard the order, this procedure permits the Health Department legally to perform the work without consent of the owner or occupant, and this in turn gives protection to the other adjacent buildings which might

be adversely affected by the omission of control measures on the one structure. This has provided for a definite continuity of operations, the lack of which would have caused disruption of plans and progress.

In presenting the work agreement, the owner or occupant is given the option of performing the work himself, to contract with a private firm, or to contract with the Health Department. Should the latter option be accepted his signature is secured on the work agreement which by virtue of good faith obligates the Health Department to perform the necessary work for a charge not greater than the estimated cost. If the former options are chosen the owner or occupant is given written minimum specifications for rat proofing and is advised that in-progress and final inspections will be made to determine compliance with requirements for both rat proofing and eradication.

3. Rat Proofing:

In this phase all the accepted principles, as based on the habits of rats, are employed. In general vent stoppage, the protection of exterior building surfaces is practised as originated by the Georgia Department of Public Health, with relatively little interior work being done. However, there are many situations, brought about by the condition of a building or the nature of the business carried on therein, which require complete rat proofing of interior surfaces and fixtures as well as exterior. Experience has indicated that a combination of inside and outside work, with emphasis placed on outside rat proofing, is the best economical general plan to follow.

Interior rat proofing is a second defense line, in that it discourages a reinfestation of rats which may enter a building accidentally such as in merchandise shipments or through open doors, and it facilitates eradication by

eliminating harborage thereby making rats more vulnerable to eradication measures.

Special emphasis is placed on permanency of rat proofing with consideration logically being given to economy. Repairs or adjustments are made to any item on a building prior to installation of rat proofing sufficient to insure that the life of the item will then correspond to the life of the rat proofing. Sound construction methods are used which with good workmanship produce permanency and neatness.

The electric power and communications utilities are coöperating in the rat proofing work by sealing all underground cable conduits, thereby preventing the travel of rats underground from one block or section to another or from manholes into buildings, and they are accelerating their program of above-ground wire and cable removal, which eliminates many exterior rat approaches to buildings.

4. Removal or Clean-up of Harborage:

During and before the application of rat proofing, harborage inside buildings as is caused by improper storage of goods and discarded materials is removed from the premises or restacked in such a manner, elevated from the floor and away from the walls, that it will no longer afford rats hiding and nesting places. Results thus far indicate that this procedure is a major factor in reducing the load on the eradication crews and in minimizing the cost in many cases.

Removal and clean-up of harborage involves labor for the most part with materials being used in cases where it is desirable to construct elevated racks for usable merchandise storage. The expenses in this connection are properly chargeable to eradication rather than to rat proofing.

Coöperation with the Fire Department has in many specific cases proved

its value to this phase. In enforcing that part of the typhus control ordinance which prohibits the accumulation of rat harborage such as rubbish, this department through its organized fire prevention inspection service has assisted greatly.

5. *Rat Eradication:*

This phase requires a maximum of knowledge, ingenuity and perseverance. Measures currently employed are trapping, poisoning, and gassing.

Trapping with steel traps and wooden snap traps has produced the majority of rats obtained. Conventional procedures are used which involve setting traps in known rat runs. The longer trapping is continued the more difficult apparently it becomes to catch rats. This is probably due to the reduction in numbers, to a change in the location of their runs, and to their avoidance of traps, which demonstrates an increasing suspicion or wariness. To increase the efficiency of trapping, ordinary baking flour in which rat foot prints are readily visible is used by trappers to determine the recent presence of rats. The flour is carried by the trapper in a small cloth sack and is spread smoothly with a trowel along known or suspected rat runs. Its use as the final step in determining whether or not a building is rat free is highly important. Six instances have already been noted of buildings where the catch of rats in traps dropped to zero remaining there for as long as 7 weeks. In one of the cases even a thorough visual inspection by several trained persons (without the use of flour) failed to disclose the definite and positive recent presence of rats, while in the others it was observed only with effort. Flour was then placed in the buildings at various points but particularly around the traps. Inspections the following day revealed the presence of rat tracks in all the buildings, and where tracks were seen around

the traps they demonstrated that rats had approached the trap to within a few inches and had then withdrawn or had gone around it. This demonstrates the value of flour and clearly indicates that a fallacy exists in assuming a building to be free of rats on the strength of a zero catch with the use of traps even over a rather long period of time.

Each trapper is assigned a route which he covers daily. It has been found that an increase in the catch of rats will result in most cases if trappers are changed from one route to another occasionally and if all traps are sprung, or completely removed and replaced from time to time. The changing of trappers has the further advantage of providing men who are acquainted with routes other than their own, hence should a trapper be absent from duty the covering of his route will be made more effective and convenient.

Poisoning with the commonly used poisons and baits has been for the most part employed as a pre-rat proofing step designed to reduce the trapping burden; it is also used in combination with other eradication measures.

Gassing with hydrocyanic acid gas thus far has been confined entirely to burrows, partition walls, hollow ceilings, and to piles of rubbish or merchandise which afford rats harborage inside buildings, and some outside work has been done to reduce the chances of a reinfestation. It has been found especially valuable in conjunction with the clean-up of harborage, and will rapidly reduce a heavy rat population which might require lengthy application of other control measures to obtain the same effect. Gas is also used in buildings where the infestation has been reduced through various means but where the few rats which remain are wary of traps and bait. In this connection work at night in the kitchens of restaurants has produced results in many cases sufficient to justify the

trouble and extra work involved. Fumigation of entire buildings has not yet been attempted.

Rats obtained are tagged showing name and address of place where caught, whether dead or alive, in which type trap, or whether gassed or poisoned, on which floor of the building, and species and sex. The securing of ectoparasites and blood samples for laboratory examination has been temporarily discontinued due to the unavailability of personnel, but is considered important to the complete picture. Weekly postings showing rats caught are made on individual record sheets for each business establishment. This assists greatly in work planning.

Of the 2,349 rats caught from February 1 to October 14, 1944, 68 per cent were *norvegicus* and 32 per cent were of the *rattus* group which includes *R. r. alexandrinus*, *rattus* and *frugivorus*. Only two true *R. r. rattus* have been observed. It is interesting to note that comparable figures were obtained from a three-story restaurant where during a 9 week period 406 rats were caught, 70 per cent being norways and 30 per cent the *rattus* group.

6. Maintenance:

To date eradication measures have been completed in eleven of fourteen blocks which have been made rat proof. This constitutes sufficient work to justify and require maintenance. The City of Memphis ordinance directs that inspections shall be made of all rat proofed buildings at intervals of not more than 45 days, and that occupants shall maintain the buildings in a rat proof and rat free condition. To carry this out, one foreman has been assigned to inspection work. His duties are to note and record any evidence of rat infestation and any new openings which will permit rats to enter a building, serving the occupant with a notice to abate the conditions found. This neces-

sitates reinspections to determine compliance, and offers excellent educational opportunities.

Cases encountered which required repairs to rat proofing indicate the preference on the part of occupants is that the Health Department perform the necessary work. Since the quantity of work required in the entire area has been and probably will be negligible, the Health Department has adopted the policy of catering to this preference, submitting statements of repair costs to occupants.

However, in the case of a reinfestation a different problem is presented. This has occurred to a slight degree in several of the business buildings formerly freed of rats. It may have been caused by leaks in the rat proofing, by a few rats being unknowingly left in the building when original eradication measures were terminated, by migration of rats from an adjacent building where eradication was performed by a private firm, or by the occupant whose efforts and results are not as conscientious and effective as those of the Health Department, or by the accidental reentry of rats. Regardless of cause, this reinfestation presents a difficult and pressing problem.

Present policies are to insist that the occupant abate this condition himself or through a private contract unless, of course, it is found that the condition was the fault of the Health Department. Reasons for this are that so many cases of reinfestation to a slight degree will probably be encountered in the future that it will be impossible for the Health Department to supply the necessary personnel for this work, and further it is felt that this attitude will in time make the individual more conscious of his responsibility in the program sooner than could be otherwise accomplished.

Night inspections are made at intervals since they disclose weak points in the rat proofing which would likely not

be discovered otherwise especially as applied to doors and windows which often remain open or are blocked by display goods in the daytime. To facilitate prompt knowledge of situations where a change of occupants or remodeling occurs in buildings, thereby insuring maintenance, the municipal licensing and building bureaus advise the Health Department of permits granted in this connection.

7. *Finances:*

This function includes the keeping of records, computation of charges and the collection of money due for services rendered. For rat proofing, individual record sheets for each establishment or building are posted daily by the foremen showing actual quantities of materials and man hours used. For eradication, since the charge is based for the most part on time involved, the dates of the beginning and ending of eradication measures are recorded as they occur. These actual field records are sent to the office for examination after which they are no longer the responsibility of the Typhus Control Service.

The Health Department has its own purchasing and bookkeeping division, one of the duties of which is to compute charges for rat control services and to make collections. Hence, all field records together with the original estimate and the work agreement are forwarded to this division whose books are audited annually. Rat proofing charges are based on actual costs of materials and man hours, plus 20 per cent which covers depreciation of tools and equipment, transportation, and other overhead. To date, in 98 per cent of the cases the charge computed in this manner has not exceeded the contract estimate, and has at the same time covered costs. Methods of calculation of eradication charges are not so accurate theoretically but results demon-

strate they are sufficient. As the 3 month (90 day) period is used as a basis, the actual number of days during which eradication was in progress is divided by 90 and multiplied by the contract price or estimate to obtain the charge.

All statements and invoices are submitted monthly to building owners and occupants by mail. If the amount due is not paid after the third statement, the case is referred to the legal department of the city. Thus far only two have been handled in this manner, the result being receipt of payment following one letter by the City Attorney.

One of the most necessary and convenient financial arrangements currently in use is a petty cash fund from which small emergency purchases are made. It is available for use by all field foremen and has many times prevented delays.

Through November 1, 1944, approximately \$18,900 appeared on the books as the total of charges to property owners and occupants for rat proofing and eradication work done. Of this, 79 per cent has been collected. The remaining 21 per cent represents accounts receivable but not overdue.

The average cost of rat proofing to property owners to date has been \$86.54 and the unit cost per business establishment has been \$47.76. These figures are based on 299 establishments owned by 165 individuals. To install \$1 of rat proofing materials, \$2.10 in labor (3.2 man hours) has been required. The average cost of eradication to 147 building occupants has been \$31.51.

PERSONNEL AND EQUIPMENT

Comprising present personnel under the direction of a public health engineer are three field foremen whose duties are to supervise the work crews in rat proofing and eradication. Of these, one acts as general foreman who in addition

to his other duties posts field records and makes original surveys and estimates. Also assigned to the program is a sanitarian who presents the work agreements to property owners and building occupants, and further assists in maintenance inspections and educational work. Twenty-two colored common laborers are currently employed, 12 being assigned to rat proofing, 8 to eradication and 2 to special work which includes maintenance. Stenographic and filing services are provided by the Health Department office.

Equipment is composed of one automobile for contact work, one $\frac{1}{2}$ ton open pickup truck for errands and light hauling, one $1\frac{1}{2}$ ton dump truck for heavy hauling and two $1\frac{1}{2}$ ton stake trucks covered with waterproof tops and completely equipped with sheet metal bending brakes, tools and materials usually sufficient for a day's operations. All tools are furnished the workmen by the Health Department.

A storage yard of $\frac{3}{4}$ acre area located convenient to the business district is provided with a materials' storehouse and workroom, a field office, and parking space for the trucks.

GENERAL ASPECTS

Educational measures, public and personal, are and will be continuous. As a medium of presenting progress reports, pictures, special humorous and serious stories about the program, facts and other material, the local newspapers are very coöperative and are frequently used. Consideration is being given to obtaining "spot" announcements on the radio. The Chamber of Commerce and Civic Clubs also serve as effective mediums for education. To provide an official meaning for educational measures, especially with reference to building occupants who compose the group most concerned presently, the Health Department has prepared leaflets giving the essentials of rat con-

trol, sketches showing proper merchandise storage methods, and letters which are mailed to occupants upon completion of rat control work advising them in a friendly yet official way of their responsibilities for maintenance. Personal contact work is constantly in progress during daily routine field operations.

Official agencies, such as the U. S. Food and Drug Administration, the municipal Fire, Garbage, Building, and Police Departments, and the Memphis Light, Gas and Water Division which is municipally owned, are coöperative and helpful in every respect. Through their daily routine inspections of premises they are able to secure information of value to the program and are in a position to carry out extensive rat control education.

It is recognized that a rat problem also exists in the residential section of the city, and that for a control program to be complete it should be city-wide in its coverage. At the present time only advice to the householder can be offered, which is generally not satisfactory and produces little of permanent value. Plans for handling this include, when conditions will permit, attention to refuse storage and removal, harborage elimination, regular inspection services, and rat proofing in all sections of the city. Another problem is presented by future building construction, the solution of which will be the inclusion in the municipal building regulations of a rat proofing code which is presently being prepared.

A rat control program is one which is valued in the public eye solely by the visible results obtained in rat elimination and not by any array of figures which may be compiled. In consideration of this, sound principles of planning, administration, and execution must be employed. It may well be emphasized at this point that in the operation of programs of this nature

there are two basic requirements, to which all others may be considered secondary although necessary, and without which success cannot be enjoyed. These may be stated as (1) quality in performance of work, and (2) the understanding, coöperation and support of every individual or organization concerned. The first is assumed obviously to be a necessary requirement; however, unless care is exercised to avoid pressure from various sources, quality may be sacrificed for speed with failure, temporary or permanent, as the result. The latter involves appreciation by the people individually and collectively, of the magnitude of the problem of rat control, their complete and voluntary assistance and participation in it and the support of the local administration. Public support may come only with the passage of time, but the attitude of those in authority locally should be positive before the beginning of a program. They should understand the problem, be prepared to provide all the

requirements for its solution, and should be willing to support its permanent maintenance.

Rat control programs are by nature long-range, and in looking to the future it is believed that with proper planning and execution, the beginning which has been made can be expanded into a city-wide program, complete in its effectiveness. It may well be that in future years the Health Department can withdraw from performing actual rat control work, confining activities entirely to inspection services as is now the practice with respect to plumbing and electrical installations.

The acceptance and absorption of health education by the public, whether forced or voluntary, through practical and successful demonstrations, is the major factor on which results depend in any program, but especially one of rat control where the public itself is so closely associated with and responsible for the very existence of the problem.

International Health Organization

The Senate Committee on Labor and Education has reported favorably on the Senate Joint Resolution for forming an international health organization and recommends its early passage by the Senate. The resolution endorses the San Francisco United Nations Conference plan for an international health organization and requests the President to urge its prompt formation upon the UNO. A recent State Department Conference of Medical experts and civic leaders suggested the following functions for the international organization.

- a. World-wide collection of disease statistics as a basis for control of epidemics
- b. Standardization and control of drugs and other therapeutic agents
- c. Centralization, consolidation, and distribution of health and medical knowledge
- d. Assistance to national health services in controlling diseases at their sources and stimulation of further development of public health services

This committee pointed out that "Disease does not respect national boundaries . . . thus to protect ourselves we must help wipe out disease everywhere."

Outbreak of Infectious Hepatitis, Apparently Milk-borne

W. J. MURPHY, M.D., AND L. M. PETRIE, M.D., F.A.P.H.A.

Georgia Department of Public Health, Atlanta, Georgia

AND

SAMUEL D. WORK, JR., M.D.

Forsyth, Ga.

OBSERVATIONS with respect to the spread of infectious hepatitis^{1, 2, 3} have generally indicated person to person transmission and have led many to believe that the disease spreads by droplet infection. On the other hand, from the results obtained by Cameron,⁴ MacCallum and Bradley,⁵ Findlay and Wilcox,⁶ Havens, Paul and van Rooyen,⁷ and others,^{8, 9, 10} in the experimental transmission of infectious hepatitis, it appears that the disease can be transmitted artificially to man by a number of routes. Furthermore, it appears that the icterogenic agent is present in the feces of the patient and that the disease can be produced in man by feeding such material in capsules. These findings suggest that under natural conditions food and drink may serve as vehicles for transmitting the infective agent and, in so far as water-borne transmission is concerned, they are supported by the observations of Neefe and Stokes,¹⁰ and others.¹¹

The purpose of this report is to present epidemiological evidence that the icterogenic agent of infectious hepatitis may be transmitted by milk. The observations reported here are based on a study of a small outbreak of 10 cases which occurred in Forsyth, Ga., during the period of May 21 to June 28, 1945. The study was made at the request of

the attending physician (S.D.W.) who had observed that all of the patients drank milk supplied by a single dairy.

The diagnosis of infectious hepatitis was based largely on the clinical picture which was quite similar to that usually described. The onset was gradual with fever, malaise, headache, and anorexia, followed shortly by epigastric distress, nausea, and usually vomiting. In several patients abdominal pain was quite marked while tenderness on the right side was generally observed. In most cases the acute symptoms subsided prior to the onset of jaundice which appeared after 3 to 10 days. With few exceptions, the jaundice lasted less than 2 weeks and was accompanied by characteristic changes in the stool and urine. None of the patients gave a history of previous injections of homologous blood products. Blood from 3 of the patients taken 3 to 4 weeks after the onset gave negative agglutinations with antigens of *Leptospira icterohæmorrhagiae*. The tests were made in the laboratories of the Georgia Department of Public Health, Atlanta, and of the Fourth Service Command, Fort McPherson, Ga.

In view of the apparent association of the outbreak with a single milk supply, visits were made to all homes supplied by that dairy. At each home

an epidemiological form was completed which included the household roster, history of illness, occupation, sources of water, milk, and other foods, neighborhood contacts, contacts with cases, school and church attendance, public gatherings attended, and other similar data. Subsequently, a canvass of the town was made in which every eighth home was visited, exclusive of those served by the dairy. During this survey information was obtained from 70 families with reference to the household roster, source of milk, and history of illness. Inquiries were also made as to any recent illness in the neighborhood or any past illness suggestive of infectious hepatitis. When such illness was reported, a visit was made to the case in question.

During the current year, infectious hepatitis was known to have occurred in only one household in Forsyth prior to the outbreak in May and June. Two cases occurred in that family. The date of onset of the second case was March 7, while that of the first, although indefinite, was at least several weeks earlier. The source of the original case was not determined but it was known that prior to his illness he had visited in another town where the disease was occurring. This family appeared to have had nothing whatever in common with those involved in the subsequent outbreak, and if any contact occurred it was purely casual.

The outbreak in May and June involved 8 households, 6 of which had single cases. The dates of onset for the first and last cases were May 21 and June 28, respectively. Onsets by weekly intervals beginning with May 21 were as follows: 1, 1, 1, 4, 2, and 1.

From inquiries relating to contact between the different households, it was learned that members of 4 of them had had occasional visiting contact with each other but not with the remaining 4 families. Of the latter, members of

only 2 appeared to have had more than casual contact in the past.

As for the patients themselves, histories of exposure were obtained from some but not from others. The 2 earliest cases appeared in widely separated households which had little in common. Neither of the patients reported any previous exposure, and only the second appeared to have had contact with any of the cases which followed. The fourth and sixth cases apparently had no contact with any of the others. Each of the remaining patients gave a history of exposure to one or another of the group but, in most instances, contact was limited to convalescent cases while in some it preceded the onset of symptoms by such a few days that person to person transmission could be assumed only on the basis of an incubation period much shorter than that usually observed. In view of the experience of other contacts, however, this did not appear likely. Under similar conditions of exposure, the disease failed to spread to neighborhood contacts. Many neighborhood children had been exposed to various convalescent cases but, as of August 15, none of them had shown any symptoms of illness. Moreover, the disease did not spread readily among familial contacts. In only 2 households did second cases appear and these developed after intervals of 13 and 29 days. On the whole, the evidence relating to contact spread did not appear sufficient to explain the outbreak on that basis.

With respect to a common source of infection, evidence tending to incriminate any food or drink, except milk, was entirely lacking. Foods were obtained from several different sources and were prepared individually in each of the various homes. Only 3 of the patients had eaten meals away from home. There was no history of attendance at any common gathering where

food or drink was served. As for water, all homes in Forsyth are supplied from the same source. There was no evidence of contamination and, furthermore, the observed distribution of cases along a single milk route is not consistent with water-borne transmission. The most significant factor encountered appeared to be the common milk supply.

The people of Forsyth obtain milk from many sources. Five dairies supply the needs of approximately one-half of the population, while the remainder obtain whole milk from numerous small producers, canned milk from local stores, or none at all.

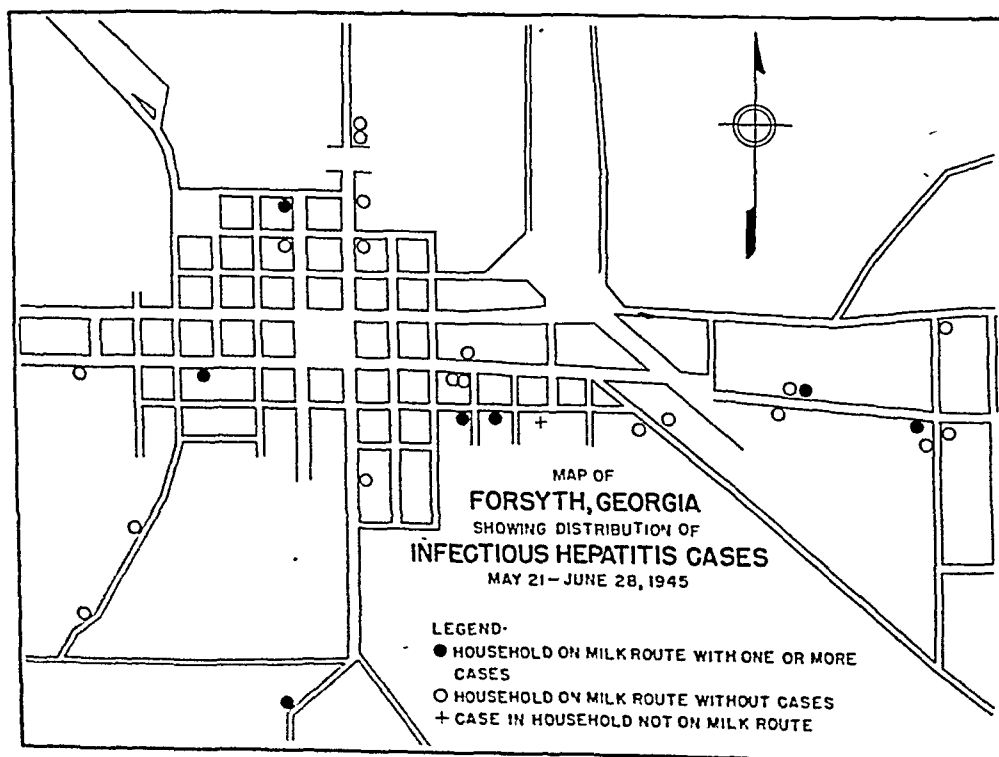

Based on the sample population obtained during the canvass, there are 586 households with 2,390 individuals in Forsyth. According to the United States Census, the population in 1940 was 2,372. The dairy under suspicion supplied raw milk to 26 households with 114 consumers, the figure in each instance being slightly less than 5 per cent of the total. The latter figure includes 4 persons who were not perma-

nent members of any of the 26 households but who ate so frequently in one or another of them that they might well be considered as regular consumers of the milk.

Of the 8 households involved in the outbreak, 7 were supplied with milk by the dairy in question. Moreover, the single case in the remaining household drank milk regularly in the home of his grandmother who was a daily customer of the dairy. One of the 10 patients actually lived in another city some 20 miles away but divided her time between her own home and that of a relative in Forsyth who was served by the dairy. From April 26 to the onset of her symptoms on June 13, she visited in Forsyth every week. During that period, no known cases occurred in the city in which she lived.

The 26 households supplied by the dairy are widely scattered throughout the town. This is shown in the accompanying map. Similarly, the households with cases are widely scattered.

As usually observed, the cases oc-

curred chiefly among those under 20 years of age. Below are shown the attack rates by age for the 114 persons who were regular consumers of the milk.

Age (Years)	Number Persons	Number Cases	Rate per 1,000
Under 20	38	9	236.8
20 and over	76	1	13.1
Totals	114	10	87.8

Of the 10 cases with frank jaundice, 2 occurred in preschool children, 5 in school children, and 3 in persons above school age. In addition to these, 4 other individuals in the group gave a history of symptoms somewhat similar to those described above but without the appearance of jaundice. They were all under 20 years of age.

In contrast to the findings in the consumer group, only one suspicious case was found among the remaining population of Forsyth. Late in June this child developed symptoms of nausea and vomiting and a slight temperature. At the same time, it was thought that she appeared more deeply tanned than usual. Recovery was complete in 3 days. The child was not seen by a physician and the symptoms were too indefinite to establish a diagnosis. Three weeks prior to the onset, the mother of the child visited one of the frank cases of hepatitis. Other than that, there was no history of contact with any known case.

The apparent absence of infectious hepatitis among those who did not drink the milk is quite striking. There are approximately 900 persons below the age of 20 years in the non-consumer group. Had these experienced the same attack rate as those who drank the milk they would have contributed 213 cases.

The 10 frank cases in the outbreak developed over a period of more than a month. This implies either a great variation in the incubation period of the disease or the infection of different patients at different times. The latter

possibility would have required contamination of the milk on more than one occasion. In view of the methods employed at the dairy, that possibility did not appear unlikely.

The dairy is located 3 miles from Forsyth and consists merely of an ordinary barn, completely devoid of all sanitary conveniences for handling milk. Approximately 100 feet from the barn is the home of the dairyman. A second house nearby is occupied by a family of relatives who moved from a neighboring state during the month of March.

No recent illness had occurred in the dairyman's family except for a mild "gastric upset" in one of 3 children which lasted for only a day or two. In the neighboring family, however, 2 cases of infectious hepatitis occurred during April and May. The symptoms in both patients were very similar to those described above. It was not possible to obtain exact dates of onset, but apparently the first case developed prior to April 15 and the second one toward the latter part of May. During this same period a third member of the family developed suspicious symptoms, but the history was too indefinite to establish a diagnosis. The source of the original case was not determined but her symptoms began within a week or two following her arrival in Georgia. There was no history of contact between these cases and those which subsequently developed in Forsyth.

This family lived in intimate contact with that of the dairyman, but apparently did not assist in caring for the milk or the utensils. Due to the primitive conditions under which the milk was prepared for delivery, however, it is possible that contamination may have occurred in other ways.

The cows were milked in a yard adjacent to the barn. The milk was then carried to a table located in the open near the barn and was simply poured

into the bottles. Everything was done by hand without any apparent attempt to prevent contamination.

Water for washing the utensils was obtained from an open, chain and bucket, dug well located about 20 feet from the table on which the milk was handled. Contamination of the well could have occurred from surface drainage or from the hands of anyone who raised a bucket of water. Experience with wells of this type has shown that in practically all instances the water shows evidence of contamination and, therefore, no samples were collected for bacteriological examination.

Located less than 100 feet from the well was a dilapidated surface toilet which was used by both families. Drainage from that point did not appear to be in the direction of the well. Apparently, however, it was not a rare practice for urine and feces to be deposited elsewhere on the surface of the ground.

Flies were numerous and were much in evidence during milking hours. They had easy access to the toilet as well as to the milk bottles and all other utensils. This combination of circumstances—numerous flies, insanitary surroundings, and unprotected food—has previously been noted in connection with an outbreak of infectious hepatitis.¹²

It is apparent that conditions at the dairy were such as to make it possible for the infective agent to gain entrance to the milk supply. It may have been carried by flies or it may have reached the milk through the water supply. Moreover, in view of the intimate contact between the two families, other possibilities cannot be excluded. In any event, contamination might well have occurred on more than one occasion.

SUMMARY

The evidence gathered during the course of this investigation, while purely circumstantial in character, points quite

definitely toward a single milk supply as the source of the outbreak. The sequence of events and the distribution of cases follow the general pattern observed in milk-borne outbreaks of other diseases. It was established that, prior to the outbreak, at least 2 cases of infectious hepatitis lived in close proximity to the source of the milk supply. Conditions at the dairy were such that contamination of the milk was possible. Subsequently, within the limits of the incubation period, cases appeared among consumers of the milk but not among non-consumers who were 20 times more numerous. Considering the conditions at the dairy, together with the observed distribution of cases, the possibility of the outbreak being unrelated to the milk supply appears to be remote.

MAZÝCK PORCHER RAVENEL

WITH the death of M. P. Ravenel on January 14, 1946, there passed one of the very few survivors of a unique band of pioneers—men who brought the new science of bacteriology to the United States, and who built upon its firm foundation the modern practices of public health.

Ravenel was born at Pendleton, S. C., some eighty years ago,¹ of a French Huguenot family which has given to its state and nation a remarkable number of men of distinction in science and in medicine. He took his medical degree at the Medical College of South Carolina in 1884, and studied at the University of Pennsylvania, at the Pasteur Institute, at Halle and Genoa. He taught at his medical alma mater, and practised medicine in Charleston for six years. In 1895, he was the first director of the Hygienic Laboratory of the New Jersey State Department of Health. Between 1896 and 1907, he worked in Philadelphia, teaching at the University and serving as bacteriologist of the Pennsylvania State Live Stock Sanitary Board and as Chief of the Laboratory of the Phipps Institute. In 1907 he went to Wisconsin as Professor of Bacteriology; and in 1914 became Professor of Preventive Medicine and Medical Bacteriology, and Director of the Public Health Laboratory at the University of Missouri, a post which he held until 1936.

The major part of his life was spent as a teacher (with time out for service as a Major and Lieutenant-Colonel in the Army Medical Corps during the first World War). His research contributions were chiefly in the field of diseases common to animals and men (anthrax, rabies, and tuberculosis).

While with the Pennsylvania Live Stock Commission, he demonstrated the transmissibility of bovine tuberculosis to man (1902); and, in 1908, at the Sixth International Congress on Tuberculosis, courageously and successfully challenged the great Koch on this point. He made substantial contributions to our knowledge of milk sanitation and was an early and ardent champion of pasteurization.

Dr. Ravenel had a fine historical perspective, and his editorship of *A Half Century of Public Health*, the Jubilee Historical Volume of the American Public

Health Association (1921) gave us a record which will always remain a classic in the history of our science.

This was but one of many services which Ravenel rendered to the Association. He was its President in 1920; and from 1924 to 1941 was the Editor-in-Chief of this *Journal*. He took it over as "an ordinary association record book" and handed it on as "the outstanding public health publication in this country."² In the entire history of the *Journal* no one man, or any group of men, has made such significant contributions to its success as Dr. Ravenel.

What a man is, is even more important than what he does. Ravenel's great contribution to his colleagues and to the cause he served was Ravenel. In the remarkable tributes paid to him on the occasion of his designation as Editor Emeritus five years ago,³ there recur such phrases as "vigor," "devotion," "integrity," "forthrightness," "uncompromising scholarship." He did not suffer fools or blunderers gladly. He "punctured balloons" with ardor. He was a "paternal castigator" of the careless and inexact. These phrases help to build up a picture of the Ravenel we knew and honored—a man of wide and exact knowledge, of ardent devotion to the truth and to the causes which he served, of relentless courage and integrity. This *Journal*, this Association, and the cause of public health in the United States owe to M. P. Ravenel a deep and abiding gratitude.

PROBLEMS OF NEONATAL MORTALITY

RECENT years have brought marked reductions in infant mortality in this country, so that in some areas rates below 30 are now recorded. This result has been accomplished by a marked decline in the number of deaths occurring after one month of age, and due to gastroenteritis, acute infectious diseases, and respiratory diseases. In contrast, deaths within the first month of life attributed to natal and prenatal causes have not declined as rapidly. To the latter causes, four-fifths of infant deaths under one month of age have been attributed. It is evident that further substantial reductions in infant mortality rates await development of methods of preventing deaths commonly associated with birth injury, congenital malformations, and premature birth.

Such causes of infant deaths have long been a problem to pediatricians and obstetricians but today new knowledge seems to be available which should help us to deal with them. It is therefore of particular interest to have three of these causes—the Rh factor, vitamin K, and the rubella virus—discussed in detail in a special review article prepared for this issue of the *JOURNAL* by Dr. Edith L. Potter. Not all experts would agree with Dr. Potter's conclusions concerning the value of giving vitamin K routinely in pregnancy. The Johns Hopkins Hospital, for example, we are informed, uses vitamin K prophylactically and has not had a single case of hemorrhagic disease of the new-born in the last 10,000 deliveries, a condition not prevailing before the use of this procedure.

What does all this mean for health departments and for physicians and institutions concerned with the prevention of infant morbidity and mortality?

Dr. Potter has estimated that there were 8,000 infant deaths (including stillbirths) in the United States in 1943 due to erythroblastosis. She bases her estimates on the diagnoses made in the Lying-In Hospital in Chicago, probably a highly selected sample. In New York City, in the period of a special study of this problem, there were 65,489 live births, with 43 deaths attributed to erythroblastosis, an incidence of 6.6 per 10,000 live births. In the same period of time there were 11 deaths due to congenital syphilis, an incidence of 1.7 per 10,000. It should be noted that Rh testing is a fairly general practice in New York City and Wassermann testing in pregnancy is mandatory. Thus, under conditions probably as good as any which prevail in this country, there are almost four times as many infant deaths associated with the Rh factor as with the *Treponema*. It therefore seems important for health departments to concern themselves with the Rh problem. Some may wish to provide the private physician through their own laboratories with Rh tests, even as diagnosis of diphtheria cultures and Wassermann tests are provided. Some may supervise other laboratories in which Rh tests are done or supply materials for such testing. (The technique is simple, usually requiring only an hour's incubation at 37° C. with a potent antiserum and a satisfactory reading.) Some departments may supervise or even operate blood banks. It must be recognized that, until further control measures are developed, deaths and morbidity associated with the Rh factor will continue, but accurate diagnosis is always a first step in any preventive program.

The provision of vitamin K by health departments for the possible prevention of hemorrhage does not seem out of line with the provision of toxoid for prevention of diphtheria or of anti-syphilitic drugs. Deaths from hemorrhagic disease are equally preventable.

Certainly further study of the problem of rubella infections and congenital malformations is indicated. Albaugh¹ has recently reported that "100 per cent of the mothers who contract rubella in the first two months, and approximately 50 per cent of those who contract it during the third month, will give birth to infants with congenital anomalies." Cataracts, cardiac septum defects and patent ductus arteriosus, deaf mutism and microcephaly are common lesions, and nearly all of the infants are poorly developed and present feeding problems.

Further clinical studies on the efficiency of gamma globulin and protective sera in preventing damage due to the rubella virus are needed; and our state and city health departments are in a position to supplement such clinical investigations by detailed routine analysis of birth certificates and intensive study of infant deaths.

DOGS AND BABIES

THE State of New York is in the throes of one of the bitterest attacks on the freedom of scientific investigation which have confronted the legislature of any state in recent years. The particular form of the assault on the present occasion is a demand for the exemption of dogs from medical experimentation which is being advocated with daily iteration by an irresponsible section of the public press.

For the moment, the anti-vivisectionists have apparently abandoned their high ethical principles which would logically forbid the taking of animal life in any form. They are not concerned with the wanton destruction of malaria-carrying mosquitoes or with the slaughter of food animals. They have even forgotten the guinea pig for whom they have been so solicitous in the past. Only the canine is now singled out as having natural rights which contravene the most fundamental bases of the public welfare and which would cut short the brilliant progress of medical science in the saving of human life.

It happens that the writer of this editorial is known to all his friends as a doting dog owner; but he happens also to be a father. He knows, as every intelligent person should know, that the entire framework of modern medicine rests upon animal experimentation; and that in many lines of investigation the dog is the only animal that can provide the answers we need. This is even more true at present than it was in the past. The relatively simple problems involved in the control of diphtheria for example could be solved by studies on guinea pigs and rabbits. The elder of our readers will recall the thrilling story of the speeding of antitoxin by dog-sled to a child critically ill at Nome. Men and dogs in Alaska; and guinea pigs in the laboratories where the secrets of diphtheria were unveiled, all shared in this triumph.

Today, however, when the plagues and pestilences of the past are coming under control, the issues of human life and health depend much more upon a knowledge of physiology than of bacteriology. Here, the smaller animals—more remote in their structure from man—will not serve. The studies on nutrition which gave us victory over pellagra, the discovery of insulin which has removed the worst terrors of diabetes, the brilliant conquest of anemia by the use of liver extract—all these were made possible by experiments on dogs. Our understanding of the working of the central nervous system and the control of shock during the war and in the hospital today rests on work with dogs. So do many procedures in modern surgery. So does the testing of new and promising drugs. The clock of medical progress would be stopped by any such restriction as that proposed in New York.

As both a dog lover and a parent, I would choose my child's life or my wife's rather than my dog's. So perhaps would the dog, if he understood the emergency; for there are plenty of instances in which these devoted animals have risked and sacrificed their lives for their human friends.

This editorial was originally headed "Dogs or Babies," but such a title involves a false distinction. The canine race profits as much as the human race from the blessings of biological science. Pasteur, through his work on anthrax and rabies, was probably the greatest benefactor of domestic animals who ever lived. Millions of dogs have been saved from suffering and death because hundreds of dogs were employed in experiments on rabies and distemper. The value to dogs of experimentation with penicillin holds great promise for the future.

So both dogs and babies have a stake in this issue. Caninitarians as well as humanitarians should unite to counter a sinister attack on the pursuit of sciences which are vital to the welfare of both dogs and men. It is our hope that public health workers as well as doctors and nurses will organize to meet the challenge which has been presented in New York State.

FIELD TRAINING FOR PUBLIC HEALTH PERSONNEL

AN opportunity for studying the actual practice of functioning health organizations is an essential part of any sound academic training of public health personnel. It corresponds to the ward rounds in the last two years of the medical course; and like those ward rounds, it involves no mere observation but a critical analysis of a series of concrete problems.

In addition to this type of training, which is a normal part of the work for the M.P.H. degree, many educators and, perhaps, most administrators, believe that the prospective public health worker should have an additional period of 3 to 12 months spent as a worker-in-training in an organized health service. This is a requirement parallel with the year of hospital internship. Such field training may be received before the student takes up his formal academic work, or after that work is completed, or both. The New York State Department of Health has provided excellent facilities for preliminary in-service training, and believes that the question of whether a candidate is worth academic instruction can best be determined in advance.

A period of post-academic training of at least three months' duration is required for students in all schools of public health nursing and in several schools of public health. All the students of health education financed in recent years through the U. S. Public Health Service have been required to take such field training; and in several schools they must complete field training satisfactorily before receiving their degree. Such a requirement seems by no means unreasonable. It is based on the same assumption as that which requires a thesis from a candidate for a research degree—the assumption that the student must prove his competence not merely by passing an examination, but by demonstrating that he can actually apply his knowledge to a concrete problem.

Growing interest in such field training naturally raises the question where—and how—such training may be provided. Clearly it can only be in health services of high quality; but, in addition to such quality, it will require very special facilities in the way of supervision. Our best precedents come from experience in public health nursing and from the work of the Michigan Field Training Center operated by the State Health Department and seven local departments jointly with the W. K. Kellogg Foundation. Dr. Horning and Miss Tuttle describe this pioneer enterprise in articles carried in this issue of the JOURNAL.

It seems possible that our Committee on Professional Education may soon find it desirable to prepare standards for the accreditation of field training areas for extensive experience. The development of such areas will require a supervisory staff qualified for their direction; and it would seem reasonable to ask the U.S.P.H.S. to finance such staffs, since the benefits to be derived from their services will be more than state-wide.

SEVENTY-FOURTH ANNUAL MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION
CLEVELAND, OHIO — NOVEMBER 11

Credit Lines

NEWS ON THE POLIO FRONT

Two reports recently published by The National Foundation for Infantile Paralysis repay study. The Foundation's annual report for the year ended May 31, 1945, analyzes fully the inter-related activities, chief among which are programs of research and education. Of the total of nearly 3 million dollars expended during the year, more than \$400,000, or about one-seventh, was for research; less than \$300,000, or 10 per cent for education; and over 2 million, three-quarters of the total, for epidemics and public health appropriations, the Georgia Warm Springs Foundation, and Tuskegee Institute.

This represents perhaps the first time in history that a voluntary health agency dependent upon public subscription has found it possible to allocate such large sums to basic research. Of the total expenditures for research, over \$200,000 was for virus research in 8 universities or medical schools and one state health department, and nearly \$200,000 for research for the prevention and treatment of aftereffects in 8 universities and medical schools, one hospital, and the U. S. Public Health Service.

A significant aspect of the research and educational work of the Foundation is that it does not set up its own laboratories and institutions and thus preserves the advantages of many minds in many settings.

The second of the Foundation's reports deserving a careful study is *Facts and Figures about Infantile Paralysis*. This is a historical and statistical study. Infantile paralysis was first reported in the medical literature of the United States by Caverly, who reported its occurrence in the Otter Creek Valley of Vermont in 1894. The first major epi-

demic centered around the eastern seaboard states in 1916.

The statistical data include maps showing the distribution of polio cases in the United States for each year 1933-1944, tables showing cases and deaths for each year 1915-1943 and a variety of other tables and charts. A pictograph chart based on the 1941 Maryland epidemic shows 50 per cent of 290 cases with no aftereffects, 29 per cent with slight aftereffects and 18 per cent, nearly one in five, with marked aftereffects, and 3 per cent of fatalities. This report and the interpretive comments of the Medical Director, Dr. Don W. Gudakunst should have a wide distribution among physicians, students, and health workers.

OFFICIAL STATE ACTION ON PROBLEMS OF ALCOHOLISM

Historically the alcoholic has seldom been regarded as a public health responsibility, or indeed a public responsibility. However, there has recently been considerable activity both in official and unofficial agencies. Among the most important developments are those in official state bodies. The *Journal* is indebted to the Research Council on Problems of Alcohol for copies of its *Bulletins* from which was abstracted the following information on current state activities with respect to the problems of alcoholism.

The recent legislative sessions of several states have established Commissions or Boards for the care of inebriates.

1. The *Connecticut* Legislature of 1945 enacted "sound legislation for the study, care and treatment of alcoholics and to provide for the creation of a board which is authorized to make a study of the problem of alcoholism to make its findings public, to set up diagnostic and rehabilitation centers and to con-

duct outpatient clinics." The Act creating the Board provides for financing its work from 9 per cent of all funds received by the State Liquor Control Commission, which it is estimated will make from \$200,000 to \$225,000 available annually. The Board is authorized to study the problems of alcoholism, including methods and facilities available for the treatment, custodial or otherwise, and rehabilitation of alcoholics, and to provide for institutional care where necessary. The Chairman of the Board is Professor Seldon Bacon of Yale's School of Alcohol Studies, and two of its five members are physicians—Dr. Thomas P. Murdock, former President of the Connecticut State Medical Society, and Dr. Arthur H. Jackson.

The law setting up the Board of Trustees for Inebriates provides for commitment to the custody of the Board any habitual drunkard who has been three times convicted of intoxication, or who has lost the power of self-control from the intemperate use of intoxicating liquors. It further provides that any person who requests such assistance must be accepted for treatment by the facilities of the Board.

2. The *Alabama* Legislature of 1945 created a "Commission on Education with respect to Alcoholism," with power "to prepare and administer a program for the rehabilitation of alcoholics and the education of the public with respect to dealing with alcoholism as a disease." An annual appropriation of \$5,000 is made available. The seven-member Commission includes Dr. B. F. Austin, the State Health Officer; four other members serve ex officio as heads of other state departments. Two members are citizens without other official capacity.

3. The 1945 *New Jersey* Legislature created the New Jersey Commission for the Rehabilitation of Alcoholics and Promotion of Temperance, making \$25,000 available for the first year. The four-man Commission is made up of heads of state departments related to the problem—Dr. J. Lynn Mahaffey, State Commissioner of Health, Commissioners of Institutions and Agencies, of Education, and of the Alcoholic Beverage Control Board. The program includes a survey of current available facilities, establishment of an information and referral center, establishment of one or more clinics, and a working arrangement with courts so that cases of alcoholism would be turned over to the Commission's authority rather than be sentenced to jail.

4. In 1945, the Legislature of *New Hampshire*, by resolution, created a seven-man Commission to study alcoholism and related problems, its expenses to be charged against

the revenues of the state Liquor Commission. The new Commission is directed to gather data on the physiological, economic, and social effects of the use of alcoholic beverages, study methods of treatment and rehabilitation of alcoholics, as well as methods of preventive public education. The Commission, whose members serve without pay, is to file its finding and recommendations with the 1947 legislature.

5. The *Massachusetts* Legislature of 1943 created a special Commission to investigate the Problem of Drunkenness in Massachusetts, with special reference to determining whether medical rather than penal treatment should be recommended for alcoholics. In 1945 its 381 page report was submitted to the Legislature with recommendations. Two of these have been favorably reported on by the Committee on Public Health—one for the establishment of a state hospital for the treatment of alcoholics and one for a permanent commission to study the problem of drunkenness. However, no action has yet been taken by the State Legislature on these recommendations.

6. The *Delaware* State Post-War Planning Program includes construction of a new building for alcoholics without psychoses. This plan was presented to the State Legislature in 1943 by the Council of Presidents of all Boards of State Agencies and the Council of Executives of all State Agencies.

7. The *Illinois* Department of Public Welfare organized a "Committee on the Problem of Alcoholism" early in 1944. One building of the Chicago State Hospital has been set aside exclusively for the treatment of inebriates. This program is being carried on in cooperation with Alcoholics Anonymous.

8. A subcommittee to make a study of the entire problem of alcoholism in *Virginia* in 1944 recommended the creation of a farm and plant for the treatment of inebriates, requiring a capital outlay of \$1,000,000 and annual operating expenses of approximately \$300,000. Although the proposal had the endorsement of both the Governor and the State Hospital Board, no action was taken by the 1944 Legislature. Active efforts to pass the proposed measure are in progress in the 1946 legislature now in session.

State Liquor Control Commissions have also been active. The 1943 *Oregon* Legislature directed its Liquor Control Commission to carry on an educational program in the public schools and among the general public on the harmful effects of over-indulgence in

alcohol. It has published a pamphlet on the dangers of excessive drinking, with the arresting title "Who—Me?"

The New Hampshire Commission investigates all cancellations of drivers' licenses, for driving while drunk, for information as to where they obtained liquor and in what condition they left the inn where served; and other information to serve as a basis for citing tavern keepers for violations. The latter are thus impressed with their responsibility for preventing drunken driving.

As Dr. Paul B. Brooks said in his column of December 24, 1945, before retiring from the *New York State Health News*: "Yes, sir. Things are stirring in the alcohol line and it ain't just cocktail shakers. Folks are coming to recognize that it's a health and not a moral problem. And it's like world peace: When the interested parties can agree on the general principles of a program—they can't expect perfection but there's hope of getting somewhere."

RHEUMATIC FEVER—ARE WE DOING ENOUGH?

In "Facts about Rheumatic Fever," written in simple, lay language, the Children's Bureau tells all of us, particularly parents, what we need to know about rheumatic fever, what is being done through state programs for the care of child sufferers from the disease, and what is still left undone. Rheumatic fever is serious because it kills more school age children in the United States than any other disease. For every child who dies there are many more who have long drawn-out attacks lasting many months. There are simple facts about the prevention and care of rheumatic fever and a statement of the state programs authorized by the Social Security program, provided local and state agencies initiate such programs and seek federal aid. The program has included care of children with rheu-

matic fever only since 1939. By May, 1945, 18 states had approved programs—diagnostic services, medical care, convalescent and rehabilitation services. Even these reach the children of less than 10 per cent of the 3,070 counties in the United States.

STATE HEALTH DEPARTMENTS' CONCERN WITH SCHOOL HEALTH

The concern of state health departments with school health programs is highlighted by the fact that two state health departments—Arkansas and Oklahoma—have each given over two recent bulletins to the discussion of school health problems. The September issue of the *Arkansas Bulletin* summarizes the Summer Workshop on School and Community Health Education held at Arkansas State Teachers College and attended by 71 teachers from 50 counties. The subject matter was provided by the State Department of Health and the educational techniques and procedure by the Department of Education. Scholarships were made available by the Children's Bureau. The November issue of the same bulletin summarizes the report of Dr. George M. Wheatley, "Present Status of School Health Service," given at the 1945 Conference of State and Territorial Health Authorities.

The October *Oklahoma Health Bulletin* is devoted entirely to school health subjects, a general discussion by the State Health Commissioner, Dr. G. F. Mathews, and one by Governor Kerr on the importance of adequate school sanitation. Other articles discuss the function of the public health nurse, and dental care of the school child. The November issue continues the subject with a discussion of the teacher's responsibility and a description of a school health program in a two room rural school in Seminole County.

From California also comes word of activity in the school health field. Dr.

George M. Wheatley, Secretary of the School Health Section, has sent Credit Lines editors a copy of Recommendations Relative to the Administration of the Health Program and to Requirements in Health Education for the General Secondary Credential in Teacher Training Institutions. These recommendations grew out of a cooperative community health education workshop held at Huntington Lake last summer. The State Departments of Public Health and of Education jointly sponsored the work, funds having been made available by the W. K. Kellogg Foundation. Also at hand is the September 15-30 issue of *California's Health* of the State Health Department, which, "in response to requests from local health departments" gives "suggestions concerning an educational program to precede and accompany school immunization and tuberculosis case finding programs."

ANNUAL REPORTS

Homer Folks, Secretary of the State Charities Aid Association of New York, takes the occasion of the 1944 annual report of his organization to summarize some of the health and welfare needs that have been crystallized by the war. They are:

1. The vast extent of mental and nervous difficulties about which useful things may be done. The fact that nearly one-third of rejections by Army induction boards were for mental and nervous factors indicates conditions about which we can no longer tolerate relative inaction.
2. Public health looms larger and larger as one of the greatest opportunities which any country, governed by an enlightened public opinion, must embrace.
3. Purchase of health and welfare of school children is a prime investment, as shown by the poor condition of so many of the 13-year olds.
4. Medical care, however excellent its quality in many areas, has obviously not been availed of soon enough and seriously enough by a considerable proportion of the American people. They cannot afford to fail to take steps to change such conditions.

The report of the National Tuberculosis Association for the year ending March 31, 1945, celebrates the creation of a Division of Tuberculosis Control in the U. S. Public Health Service as the natural culmination of the Association's many years of activity. It also announces a news letter, "Que Hay de Nuevo." Issued three times during the year, it reports new developments in tuberculosis control among Spanish speaking people. Financial aid was also given for reestablishing the work of the Philippine Islands Anti-tuberculosis Society, interrupted by the war. Field service was provided for the St. John's Rotary Club in organizing the Newfoundland Tuberculosis Association which conducted the 1944 Seal Sale for the province.

The association expended over half a million dollars during the year and ended with a surplus of approximately a quarter of a million. It expended \$25,000 for social research and \$65,000 for medical research. For special work in tuberculosis among Negroes \$20,000 was spent, and about \$3,500 for work among Spanish speaking people; \$10,000 was given to the International Union Against Tuberculosis.

Many Paths . . . One Purpose—The 1944-1945 report of the Milwaukee County Council of social agencies is notable for typography, illustrations and format, and shows what can be done by an imaginative use of present-day processes that are cheaper than printing. Its title too, is descriptive. "We stand," says the report, "in the front line of service to man's unchanging, human needs in a world of crashing change."

MEDICAL SUPPLY HOUSE PAMPHLETS

Pamphlets of several of the drug and medical supply and other concerns have been accumulating on the Credit Lines desk. It seems fitting to mention some

of their contents in recent months. The following are nominated for honorable mention:

What's New, of the Abbott Laboratories for its series of War Paintings.* The October and November, 1945, issues respectively are numbers 8 and 9 in the series, the China-Burma-India Theater with paintings by Howard Baer, and the Southwest Pacific, by Robert Benney. These paintings are also being shown at various exhibitions throughout the country. If anyone is still unable to visualize the horrors of war, let him see these paintings.

Therapeutic Notes, of Parke, Davis & Co. For its general excellence of workmanship and color illustrations. The cover of its October, 1945, issue symbolizes Roentgen's discovery of the X-ray on November 8, 1895.

The Prevention of Communicable Diseases in Childhood, of Lederle Laboratories, with sprightly pastel color illustrations and graphs tells briefly and simply the story of immunization in diphtheria, scarlet fever, measles, smallpox, tetanus, whooping cough, typhoid.

Scope, of The Upjohn Co. for its Basic Science Review Service Series, No. 12 of which describes *The Anatomy of the Adrenal Glands*, illustrated with beautifully executed drawings in color. The same issue has an article on Oral Penicillin.

Roche Review, of Hoffman-La Roche, Inc. and Roche Organon, Inc. The September and October, 1945, issues summarized in tabular form the literature on the use of vitamins and drugs, including photographs of the crystalline forms of various vitamins.

All of these have excellent paper, format, typography, and color photography.

* This series has now been published in one volume, *Men Without Guns*, by DeWitt Mackenzie. 155 pp. 177 illus. Obtainable from The Book Service. Price, \$5.00.

DENTAL HEALTH IN INDIANA

The October issue of Indiana State Board of Health *Monthly Bulletin* is its first "dental issue" and is devoted entirely to the problem of dental public health. Included among more general articles is one on diet control of dental caries, a geographic fluoride survey of Indiana ground water supplies, an analysis of the distribution of

dental students and dental care, and a story of dental programs carried on by Indiana industries. It ends with an Edgar Guestian "pome" called "Farewell, My Sweets!" by Dr. Thurman B. Rice.

ORCHIDS TO BALTIMORE

Credit Lines recognizes the outstanding success of *Baltimore Health News*, the monthly publication of the Baltimore City Health Department, Huntington Williams, M.D., Dr.P.H., Commissioner, for personalizing the staff and the program of the Department of Health. The December, 1945, number, for example, reprints photographically an editorial from a local paper on the retirement of the Director of School Hygiene in Baltimore, notes the completion of 40 years of continuous school health work of another staff member, gives credit to the alertness of the chief dietitian in one of Baltimore's hospitals in averting an outbreak of food poisoning, pictures a laboratory staff member now with the Medical Corps of the Navy, and gives an illustrated sketch of the career of a young woman now directing medical research at the Communicable Disease Hospital in Baltimore.

The people of Baltimore will not fail to be more appreciative of the individuals who serve them through the City Health Department and their specialized activities because of this well directed and executed policy of *Baltimore Health News*.

RACE PRACTICES OF NATIONAL ASSOCIATIONS

The American Civil Liberties Union has recently completed a survey of race practices in some 150 semi-public national associations, not of a religious or fraternal character. The survey was made by questionnaire regarding which the report says "It is clear that precise listing is impossible without knowing

more detail than a simple questionnaire affords, and without examining through additional evidence whether professions of non-discrimination actually so work out in practice." Also the questions were devoted largely to discrimination against Negroes, with only one general question as to other minorities (aliens, citizens of oriental ancestry).

With these qualifications 93, two-thirds of 141 associations, reported no racial segregation or discrimination, 40 reported segregation only in local or state chapters, 3 reported discrimination but not segregation, 3 reported complete segregation and 2 exclude Negroes altogether.

The American Public Health Association is among those of a list of 9 health and medical associations that have no policy of racial discrimination in admission to membership. Among others are the American Heart Association, American Hospital Association, American Medical Women's Association, and the American Psychiatric Association.

TOWARD THE CONSOLIDATION OF LOCAL GOVERNMENTAL UNITS

Taxation, of the Minnesota Taxpayer's Association for August, 1945, reports an interesting study in Blue Earth County, Minnesota. This is one of three rural county studies sponsored by the Spelman Foundation and requested by the U. S. Bureau of the Budget. The Director of the Budget wanted to find out whether federal sums to local communities for various purposes, among them local health service, were weakening or destroying local government.

The study was carried on by a local council without direction or supervision from Washington, the State Capitol, or any other source. It found in this county of fewer than 37,000 persons, 298 agencies of government with nearly 700 officers and employees. Among

them were 155 separate tax-levying units of government.

The report recommends that, save where there are widely overlapping and conflicting services, these local governmental units should be maintained and strengthened. To revitalize them, however, and encourage them wherever possible to take over some of the responsibilities now exercised by the state and local officials, the Blue Earth Council suggests a plan for the formation of an intergovernmental council in each county to serve in the first instance as a clearing house and a coordinating body. An Act of the 1943 Minnesota Legislature makes this possible by giving any groups of local governing units the right to join together to do what any one of them is empowered to do independently. Thus a great step forward has been taken, for example, in developing the climate in which the 2,700 units of local health jurisdiction in Minnesota can be consolidated into far fewer and more effective working units.

The other two counties being studied are Henry County, Indiana, and Cloquett County, Georgia. It will be interesting to see whether they too recommend strengthening of local government through intergovernmental cooperation, rather than an extension of state or federal control in local services.

WORTH ACQUIRING

And Now, Home—A series of unit programs on the reintegration of the returned soldier to community life, this pamphlet has been prepared for the use of army convalescent services, information and educational officers and organizations interested in acquiring greater knowledge of the medical, personal, social, vocational, economic, and educational problems of army air force veterans and in methods of helping the veteran to meet these problems. Basic

principles found effective both in the armed force and in existing community programs are presented, rather than "rules" since both veterans and communities are individual. Available from the Convalescent Services Division, Office of the Air Surgeon, Headquarters, Army Air Forces, Washington 25, D. C.

The Soldier Takes a Wife—Humorously illustrated and colloquially written, particularly for service men and returning veterans, this little pamphlet charts the "minefields" of a hasty marriage as well as the "clover patch" of a planned one, including proper planning for children. "When you know you've found companionship—its time to think of marriage—not any sooner," "she may be good at jive but a sad sack at the skillet," and "the health of a family can be guarded and promoted if each child is consciously planned rather than just born," are among its admonitions.

This pamphlet was prepared at the request of service medical officers and chaplains and has already been translated into Braille for the benefit of Navy blinded. It is available from Planned Parenthood Federation of America, Inc., 501 Madison Avenue, New York 22, N. Y.

Ten Years of Service for Children under the Social Security Program, August, 1935–August, 1945—This is a summary of the work done in extending health services for mothers and children

through Social Security. In three parts it covers maternal and child health, services for crippled children, and child welfare services, all of which are administered by state and local agencies, with federal financial assistance, under plans approved by the Children's Bureau. During approximately the period of the program the infant mortality rate has decreased nearly one-third, the maternal mortality rate more than one-half. Although 100,000 crippled children received care under the program, it is estimated that fewer than 10 per cent of the nation's physically handicapped children have been brought under care. As to child welfare services, only a beginning has been made in providing child welfare workers to cover every state. Available without charge from the Children's Bureau, U. S. Department of Labor, Washington, D. C.

A revision of the leaflet, *Posture, Guide for Public Health Nurses No. 5*, of the Family Health Series, published by the Department of Educational Nursing, Community Service Society, New York City, has just appeared and is well worth acquiring. Its simplicity makes it useful to parents, teachers, high school and college students, as well as doctors and nurses. It is especially planned for teachers. The price of *Posture* is 10 cents plus postage for orders of 1 to 100, 8 cents plus postage for orders of over 100. Address Community Service Society, 105 East 22nd Street, New York 10, N. Y.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

Health Practice Indices, 1943-1944—Prepared by the Subcommittee on State and Local Health Administrators of the Committee on Administrative Practice of the American Public Health Association. (3rd ed.) New York: A.P.H.A., 1945. 87 pp. Free from publisher.

This is the third edition of a booklet containing a collection of charts which show the range of accomplishments in various fields of community health services for 243 communities in 32 states and 4 Provinces of Canada, as determined from *Evaluation Schedules* submitted by these health departments in 1943 and 1944.

The third edition of this publication represents a marked improvement over the first two editions. The numbering of the lines in the charts, in conjunction with a reference table which was introduced for the first time in this edition, enables one to determine readily the standing of his health department in relation to other departments submitting schedules. The marginal notes which accompany each chart are informative and succinct.

This booklet will prove of interest to all public health workers, since it presents an opportunity to study the performance of a number of health departments from a wide geographic area. The publication will prove of special interest to local health officers, who will find these charts, in conjunction with the *Evaluation Schedule*, to be helpful as a guide to good public health practice. In like manner, directors of the divisions of local health services and directors of

divisions of specialized services in state health departments will find these charts to be useful as a basis for consultation services.

As local health departments in increasing numbers submit *Evaluation Schedules*, the charts will become increasingly meaningful.

RICHARD F. BOYD

Paths to Better Schools. *Twenty-third Yearbook of the American Association of School Administrators*. Washington: National Education Association, 1945, 415 pp. Price, \$2.00.

The improvement of professional efforts, always desired by the leaders in any field, is achieved by careful study and redefinition of goals, by intelligent utilization of new methods, and by the adaptation of procedures to changing social and economic conditions. *Paths to Better Schools*, prepared by an outstanding group of educators composing the 1945 Year Book Commission of the American Association of School Administrators, presents constructive suggestions for improving school programs, facilitating pupil learning, and modernizing the financing of public education. As stated in its foreword, "Paths to Better Schools . . . sets no final lists of goals, no infallible collection of procedures, no guarantee of success. Much of the content will not be new to those who have made the greatest strides in educational development. It should help many laymen and educators, however, to see more clearly 'what was already there, perhaps, but dim.'"

Despite the commission's modesty, as revealed in the foregoing statement, all who are interested and concerned with public education in the United States, and that should include every adult, will find *Paths to Better Schools* interesting reading and will find the viewpoints and suggestions stimulating and provocative.

Three chapters relate to school programs, one each to Physical Fitness, Preparing Youth for Occupational Efficiency, and Citizenship. The chapter on Physical Fitness, of particular interest to those concerned with health and health education, points out some of the weaknesses of programs of health service, health education, and physical education, and suggests ways by which better programs may be attained. Two particularly significant statements are: "The foundation of physical fitness is laid down in the formative period of the child's life. This means maximum protection from disease and handicaps, a joyous childhood, wholesome health habits, and a vigorous out-of-door play life." and "The great weakness in the school health service has been the failure to develop methods of preventing and correcting defects which are reported in the same frequency year after year."

For those engaged in health education, the chapter on "Better Ways of Learning" provides an excellent summary of present-day viewpoints on teaching methods. Attention is given to "(a) finding and meeting the needs of the individual, (b) democratic tendency, (c) learning by doing, (d) evaluation, (e) increased use of audiovisual aids, (f) teaching related to life situations, and (g) broader objectives through experimental teaching."

Although the parts of *Paths to Better Schools* to which reference has just been made contain information and viewpoints of special interest to those concerned with school health programs,

other sections, dealing with methods of financing school programs and of equalizing educational opportunities, should be read by all who wish to develop intelligent opinions regarding federal aid to education and the inter-relationship of federal, state, and local education authorities.

CHARLES C. WILSON

Rorschach's Test, II. A Variety of Personality Pictures—*By Samuel J. Beck, Ph.D. New York: Grune & Stratton, 1945. 402 pp. Price, \$5.00.*

In this companion volume to *Rorschach's Test I, Basic Processes* (reviewed, *A.J.P.H.*, September, 1944, p. 995), Dr. Beck has carried his exposition of the test into the realm of interpretation. Part I of the present volume is concerned with an explanation of the psychological significance of the various categories, or test factors, into which the responses of a subject to the Rorschach ink blots are classified. In Part II, analyses of the records of a group of persons representative of various intellectual and developmental levels, and a group of schizophrenic and neurotic subjects are presented.

Impressive as are the personality portraits which the author gives, even more impressive are the clinical insights which have revealed the significance underlying test responses. The discovery, for example, that a "good" form response shows an individual's ability "to direct his thinking from his higher centers, i.e., with conscious attention and discriminating judgment," the penetration into the meaning of movement responses, of color responses, and the like, are remarkable achievements. Although the necessity for constant revaluation and validation of the interpretations cannot be too strongly urged, the unique contribution of the test to clinical diagnosis is evident. Despite the book's highly technical nature, lay persons whose interests at

some point touch those of Rorschach clinicians will not fail to find it an absorbing work.

LILLIAN DICK LONG

Virus as Organism—By *Frank MacFarlane Burnet, M.D.* Cambridge, Mass.: *Harvard University Press*, 1945. 134 pp. Price, \$2.00.

"... as far as the doctor, the public health administrator, and the biological experimenter are concerned, the pragmatic necessity will remain that virus be regarded as organism—self-reproducing, varying, and surviving like any other living being." With this concept the author progresses to a consideration of the behavior and characteristics of viruses in the dynamic, evolutionary and genetic sense. Variation in a virus is considered to be selection of mutating forms, and survival is considered in the broad terms of parasitism. These ideas are carried forward into a discussion of the evolution and changes in virus diseases as a problem in natural history; it is in these sections that the book is most stimulating in seeking to interpret the history of a virus disease in terms of the agent's behavior in the host. For instance, herpes simplex and psittacosis probably represent old diseases in which the virus has reached evolutionary stability with the host; poliomyelitis is presented as a disease in the process of evolution. The discussions of influenza, smallpox and yellow fever seek also to view the broad problems presented by the respective diseases.

The book is provocative, since the author has frankly permitted himself the privilege of indulging freely in theory; for this reason the reader must guard against factual acceptance of all the ideas expressed. It serves, however, an important function in seeking to concentrate attention upon the broad concepts of epidemic disease in terms of the agent involved rather than in minutiae which at present are difficult

to interpret. It is highly recommended reading. THOMAS FRANCIS, JR.

Manual for Coding Causes of Illness According to a Diagnosis Code for Tabulating Morbidity Statistics—*Division of Public Health Methods, U.S.P.H.S., Misc. Publication No. 32.* Washington: *U. S. Govt. Ptg. Office*, 1944. 489 pp.

Here we have in as nearly perfect technical and textual form as possible what all hopeful devotees of systematic morbidity reporting and publication have awaited these many years. Since Bolduan's first public declaration of the need, potential usefulness, and practical methodology of morbidity reporting by medical institutions in 1913, down through the *Standard Classified Nomenclature of Disease*, 1938 and 1942, and the *Hospital Discharge Study of New York* by Neva Deardorff, 1933, et seq., the essential technology for coding according to a diagnosis code for tabulating morbidity statistics has been lacking, and if offered has been neither officially nor unofficially acceptable. We have the distilled essence of the whole matter admirably presented in this volume of 489 pages.

An introduction of 25 pages gives all the necessary textual description for any competent reporting or registration office. The next 25 pages gives us a morbidity code with corresponding numbers of the *International List of Causes of Death*.

From pages 51 to 126, we have a classified listing of morbidity categories with representative inclusions.

Pages 127–461 give us an alphabetical index to the morbidity code.

Pages 462–489 are devoted to three useful appendices.

If there is anything essential missing, the reviewer has not discovered the omission. This is the most important step so far made in our country toward responsible uniform comparable mor-

bidity data. The position of the United States at the next (1948) International Conference on Certified Causes of Death and Diseases will be one of greater distinction and influence because of the appearance of this highly creditable product of effective collaboration between the U.S.P.H.S. and the Bureau of the Census.

HAVEN EMERSON

Government in Public Health—

By Harry S. Mustard. New York: The Commonwealth Fund, 1945. 219 pp. Price, \$1.50.

This monograph is one in the series published for the Committee on Medicine and the Changing Order of the New York Academy of Medicine. Dr. Mustard first analyzes the conditions and problems of public health work in general. Against this background, he surveys the history, current practice, and future opportunities of government health administration on the federal, state, and local levels. The historical approach enables the reader to view the present situation as one of transition between the past and the probable future. Within this framework the study emphasizes the social and political, rather than the technical aspects of the subject.

Dr. Mustard faces squarely the trend toward increasing federal control through the Public Health Service. But the failure to combine all major national administration in the Service, with various unfortunate implications, is also carefully described.

It is recognized that the bulk of actual health service must be rendered by local departments. The fact that many communities still lack full-time

health service is viewed as the most immediate need in the entire field. The author believes that mandatory laws should be adopted in the states, requiring that approved districts set up departments employing full-time health officers. The poorer districts will require state or federal assistance, and the growing importance of the state department as an intermediary here between federal and local agencies is fully recognized.

The study is both comprehensive and critical. The reader sees the overall picture, senses progress, but is quite conscious of serious inadequacies and of improvements that are indicated. The style is admirably clear and incisive. One could hardly ask, within brief compass, for a more informative and thought-provoking account of this increasingly important aspect of modern medicine. RICHARD H. SHRYOCK

American Red Cross First Aid Textbook (rev. ed.)—Philadelphia: Blakiston, 1945. 254 pp. Price, Cloth, \$1.00; Paper, \$.60.

The revised edition of the well known *First Aid Textbook* of the American Red Cross presents a complete rewriting of previous editions, and has been greatly improved and enriched by contributions from leading surgeons, first aid instructors and research workers. It is profusely and well illustrated. With the rate of home, farm, and highway accidents mounting, and the last-named group a special menace, this textbook is a welcome and necessary tool in the hands of doctors, nurses, and the students in first aid classes. Would we had had it in 1941!

DOROTHY DEMING

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

And We Were Lucky!—Though our combat losses (325,000) in World War II exceed battle deaths in all previous conflicts, including both sides in the Civil War, our European allies suffered far greater casualties, and the enemy endured a still more huge death toll, mounting into the millions.

ANON. American Combat Losses in World War II. Stat. Bull. (Met. Life Ins. Co.). 26, 11:1 (Nov.), 1945.

National Health Bill—Current Model—If you are one of the "socialistic element in the American Public Health Association," you may wish to see that for which you are held, in part, responsible by a spokesman of the opponents of compulsory prepaid medical care. You will find here a clear analysis of the latest version of the Wagner-Murray-Dingle Bill. In the same issue of the Journal is an up-to-date statement of the Medical Association's position in the matter of medical care, and the editorial from which came the words in quotes above.

ANON. The National Health Act of 1945. J.A.M.A. 129, 14:963 (Dec. 1), 1945.

When German Measles Is Decidedly Dangerous—If mothers contract rubella during the first three months of pregnancy, congenital defects frequently develop in the fetus. Commonest lesions are cataracts, cardiac defects, deafness, and microcephaly.

ALVAUGH, C. H. Congenital Anomalies Following Maternal Rubella in Early Weeks of Pregnancy. J.A.M.A. 129, 11:719 (Nov. 10), 1945.

How Times Have Changed Department—"Furthermore, they (the

mothers) were instructed to adjust the feeding schedule to the rhythm indicated by each individual baby, rather than to maintain a strictly prearranged regimen. Even when the cause of crying was not evident . . . (they were told to) pick up the baby and try a little fondling. The soothing use of rocking chairs and lullabies was suggested."

ALDRICH, C. A., et al. The Crying of Newly Born Babies. J. Pediat. 27, 5:428 (Nov.), 1945.

Health Educator's Functions—You will find here an answer to the objection: "If almost all health work is educational and all health workers should be educators, why do we need a health educator?" Also there is a statement about what is being done to create a supply of these supernumeraries.

DERRYBERRY, M. Health Education in the Public Health Program. Pub. Health Rep. 60, 47:1394 (Nov. 23), 1945.

The Older the Sicker—Though the number of absences for both sexes decreased with advancing ages, the duration increased, resulting in an upward trend with age in days lost. You'll find a lot of useful statistics in this recording of Boston Edison experience.

GAFATER, W. M., and SITGREAVES, R. The Age Factor in Disabling Morbidity 1940-1944. Pub. Health Rep. 60, 49:1447 (Dec. 7), 1945.

In-Service Training by Participation—The "workshop" epidemic hits health administration—with a happy outcome, apparently. Six committees decide what is to go into this particular venture in staff education.

GARDNER, B. C. Staff Workshop Gets Results. *Pub. Health Nurs.* 37, 11:573 (Nov.), 1945.

It Helps Erupted Teeth, Too—Not often do we have a really controlled human demonstration. But here, two groups of Japanese were relocated—and forced to stay where put. One group was sent to a place with a fluorine-free water supply. The other to a place with water having 3 p.p.m. of fluorine. The teeth of boys and girls sent to each place were examined and two years later reexamined. The incidence of new caries developing in the fluorine group was about half that of the control.

KLEIN, H. Dental Caries Experience in Relocated Children Exposed to Water Containing Fluorine. *Pub. Health Rep.* 60, 49: 1462 (Dec. 7), 1945.

Breast vs. Bottle Again—Is mother's milk really better than cow's milk for babies? This question is answered in an impressive series of papers on vitamin, mineral, and trace element contents of both varieties of milk, metabolic studies of mothers, and growth and skeletal maturation of infants. When the series is complete the findings in favor of the breast will be irrefutable, but the bottle will still win the battle.

MACY, I. G., *et al.* Human Milk Studies (and eight related papers). *Am. J. Dis. Child.* 70, 3:135 (Sept.), 1945.

Preventive and Curative Nursing—Today nurses occupy more than half the technical positions on health department staffs: there are more than 20,000 of them, with 3,500 vacancies. What about the future? There will be less need for certain kinds of nursing—in the care of communicable diseases—but a great deal more work in mental and chronic diseases. Other changes are in store.

MOUNTIN, J. W. The Future of Public

Health Nursing. *Pub. Health Nurs.* 37, 11: 542 (Nov.), 1945.

ANTU—A new rat poison, which seems to be specific for Norway rats, is now available for use by sanitary officers. Its emetic properties make it safe for dogs (in most cases).

RICHTER, C. P. The Development and Use of Alpha-Naphthyl Thiourea (ANTU) as a Rat Poison. *J.A.M.A.* 129, 14:927 (Dec. 1), 1945.

Generously Adequate Diets for Children—Children will consume the basic foods in generous amounts if they are given the chance, and they will grow much better than if kept on a diet as deficient in these essentials as most institutional fare is, and a good many home-served meals are. As Bernard Shaw would say, "I could have told them that and saved them the trouble," but someone, I suppose, should demonstrate the probable. At any rate, the children enjoyed a year of good eating.

ROBERTS, L. J., *et al.* Results of Providing a Liberally Adequate Diet to Children in an Institution. *J. Pediat.* 27, 5:393 (Nov.), 1945.

Hopeful Note—A tardy outbreak of influenza which involved a considerable number of individuals in unvaccinated wards, but did not occur in vaccinated wards, suggests that immunity produced by vaccination may persist at least one year.

SALK, J. E., *et al.* Immunization Against Influenza with Observations During an Epidemic of Influenza A One Year After Vaccination. *Am. J. Hyg.* 42, 3:307 (Nov.), 1945.

Flight in Pure Speculation—A British M. O. H. takes a broad look at public health and asserts that we are now on the threshold of a third phase. The initial or sanitation era was followed by an epidemiologic attack upon specific diseases coupled with maternity and infant hygiene. Our new aim is

the prevention of deviations from health from whatever cause. As engineering gave way to epidemiology, so the latter will bow to sociology as the "curly haired boy" of public health administration, the essayist implies.

SAVAGE, W. Public Health and Its Debt to Experimental Medical Research. M. Officer. 74, 20:161 (Nov. 17), 1945.

Out on a Crowded Limb—First concerns of men and women who work is a job and security, but an increasing number of labor-management contracts include health insurance, which is a sign, asserts this writer, that labor has some concern about health protection, too. He predicts that labor will con-

tinue to support down-to-earth programs against V.D.

SHOSTAC, P. Notes on Industrial Cooperation. J. Social Hyg. 31, 7:481 (Oct.), 1945.

Out of This War—Our Spanish war shocked us into the control of typhoid, the first World War drove us to attempt to stamp out syphilis. The recent conflict challenges us to do as much against mental disease. An aging population, too, will change directions of public health from communicable disease and infant hygiene to chronic conditions.

WINSLOW, C.-E. A. Postwar Trends in Public Health and Nursing. Am. J. Nurs. 45, 12:989 (Dec.), 1945.

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed in future issues.

ANATOMY AND PHYSIOLOGY. By Frederic Theodore Jung, M.D., and Elizabeth Carpenter Earle, R.N. 3rd ed. Philadelphia: Davis, 1945. 829 pp. 338 illus. Price, \$4.00.

CLEVELAND MARKET DATA HANDBOOK. By Howard Whipple Green. Cleveland: Real Property Inventory of Metropolitan Cleveland, 1945. 69 pp. Price, \$2.50.

THE EFFECT OF BOMBING ON HEALTH AND MEDICAL CARE IN GERMANY. By the Morale Division, United States Strategic Bombing Survey. Medical Branch Report. Washington, D. C.: War Department, 1945. 388 pp.

ASSOCIATION NEWS

VOCATIONAL COUNSELING AND PLACEMENT SERVICE—A PROGRESS REPORT

Active contact with employers, candidates, and those seeking counsel has greatly increased recently in the American Public Health Association Vocational Counseling and Placement Service. Within the last month, before this goes to press, the Vocational Counseling and Placement Service has received and answered approximately 200 letters; office interviews average two to four daily. The Association operates this Service under a coöperative plan and with the assistance of the U. S. Public Health Service.

The Placement Service files list employment opportunities and available personnel in all spheres of public health

(public health nurses are referred to special agencies). On December 31, it listed 146 openings offered by 62 employers, as well as 82 candidates for positions. These numbers promise to increase considerably during the month of January, 1946.

The more openings and available candidates are known to this Service, the better the "clearing house" will function. Efforts are being continued to locate openings and applicants through all available channels. Readers of the *Journal* are invited to notify the Association promptly of existing openings, giving all necessary particulars.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Earl B. Miller, M.D., 111 Dean St., Woodstock, Ill., District Health Supt.
John R. Turner, M.D., 815 N. High St., Uvalde, Tex., Director, Southwestern Texas Health Unit

Laboratory Section

Arthur R. Cade, Ph.D., P. O. Box 224, Rutherford, N. J., Bacteriologist, Givaudan-Delawanna, Inc.
Joy B. Cross, Ph.D., University of Tex., Medical Branch, Galveston, Tex., Research Assoc., Dept. of Preventive Medicine and Public Health
Philip Grossman, 1000 East Fern Ave., Garvey, Calif., Research Asst., Univ. of Southern California
Harold Macy, Ph.D., University of Minnesota, University Farm, St. Paul 8, Minn., Prof. of Dairy Bacteriology
Bernice Messerschmidt, City Hall, LaCrosse, Wis., Supervisor, State Coöperative Laboratory, State Board of Health
Robert I. Modica, M.S., 1535 Oakmount Rd.,

South Euclid 21, Ohio, Bacteriologist and Serologist (recently in Service)

Charles R. Smiley, 503 Doctors Bldg., Nashville 3, Tenn., Asst. Bacteriologist, Physicians Laboratories
Dorothy T. Wilson, 335 Tioga St., Trenton 9, N. J., Chemist, Industrial Research Dept., National Oil Products Co.
Ernest J. Witte, V.M.D., 350 Lafayette St., New York 12, N. Y., Student, Columbia Univ., DeLamar School of Public Health

Vital Statistics Section

Nancy H. Ampel, 138 E. 35th St., Brooklyn 3, N. Y., Junior Statistician, New York City Dept. of Health
LaVina Harrison, 4422 Third Ave., New York 57, N. Y., Medical Records Librarian, Home for Incurables
Pearl Josephson, 49 W. 96th St., New York, N. Y., Statistician, New York City Dept. of Health
Margaret S. Wright, P. O. Box 1222, Honolulu, Hawaii, Administrative Procedures Analyst, Board of Health, Territory of Hawaii

Engineering Section

- Burk Chester, Tavares, Fla., Senior Sanitary Officer, Lake County Health Dept.
 Lt. Col. Edward S. Hopkins, Sn.C., 4402 Roland Ave., Baltimore, Md., Chief, Sanitary Engineering Section, Third Service Command
 Maynard L. May, Box 177, Boca Raton, Fla., Operations Engineer, Sanitary Section, Boca Raton Army Air Field
 Perry McK. Teeple, 2321 Belote Place, Jacksonville 7, Fla., Sanitary Engineer, State Board of Health

Industrial Hygiene Section

- John J. Lareau, Dept. of Labor, LaPaz, Bolivia, S. A., Safety Engineer, Accident Prevention Section, Bolivian Government

Food and Nutrition Section

- Marjorie G. Abel, M.S., 444 E. Pau St., Honolulu 37, Hawaii, Consultant Nutritionist, Board of Health
 Rheta B. Hyatt, 925 Main St., Bridgeport, Conn., Director, Community Nutrition Service
 Edna Mae McIntosh, M.S., Gerber Products Co., Fremont, Mich., Nutritionist

Maternal and Child Health Section

- Grace E. Malone, 332 New St., Newark 4, N. J., Senior Medical Social Worker, Newark Dept. of Health
 Leon Sternfeld, M.D., 74 State St., Albany, N. Y., Chief, Bureau of Medical Rehabilitation, State Dept. of Health

Public Health Education Section

- Ruth D. Ackland, 3741 Lurline Drive, Honolulu 17, Hawaii, Acting Director of Public Health Education, Territory of Hawaii Dept. of Health
 Lucy S. Dade, Vanderbilt Univ., Mary Kirkland Hall, Nashville, Tenn., Asst. Prof. of Nursing Education, School of Nursing
 Davida M. Finney, American Mission, Cairo, Egypt, Missionary
 Leah C. Furtmuller, 511 W. 235th St., New York 63, N. Y., Secy., Committee on Visiting Housekeeper Services, Welfare Council of New York City
 Sgt. Robert A. Gegere, 227 General Hospital, APO 772, Postmaster, New York, N. Y., Venereal Disease Clinic Asst.
 Janie Herndon, M.S.P.H., County Health Dept., Spartanburg, S. C., Health Educator
 Mary Margaret Jones, M.S., 17 Ford Ave., Oneonta, N. Y., Exec. Secy., Otsego County Tuberculosis and Public Health Assn.
 Barbara L. Kahn, M.P.H., City Health Dept.,

- Public Safety Bldg., Seattle 4, Wash., Director of Public Health Education
 Aubrey Mallach, M.S., 519 Smithfield St., Pittsburgh, Pa., Secy., Health Division, Federation of Social Agencies
 Carmel A. McKay, P. O. Box 1067, Vallejo, Calif., Exec. Secy., Solano County Tuberculosis Assn.
 Gladys M. Morrison, 32 Tucker Ave., Liguanea, Jamaica, B.W.I., Health Education Officer, Government of Jamaica
 Myron Weaver, M.D., 5233 3rd Ave., S., Minneapolis, Minn., Asst. Prof. of Preventive Medicine and Public Health, Univ. of Minnesota
 Sophie P. Williams, M.A., 600 West 168th St., New York, N. Y., Exec. Secy., Washington Heights-Riverside District Health Committee
 Robert O. Yoho, M.A., 3630 W. 32nd St., Indianapolis, Ind., Director, Health Education Division, State Board of Health

Public Health Nursing Section

- Grace H. Cole, R.N., P. O. Box 158, Sanford, Fla., Public Health Nurse, Seminole County Health Unit
 Thelma Foster, 2002 Castleman Drive, Nashville, Tenn., Director, Nursing Activities, Nashville-Davidson County Chapter A.R.C.
 Lt. Mary E. O'Connor, 411 W. 116th St., Johnson Hall, New York 27, N. Y., Student, Columbia University, DeLamar Institute of Public Health
 Elizabeth R. Vickers, R.N., 131 E. Arch St., Marquette, Mich., Pediatric Consultant, Michigan Crippled Childrens Committee
 Gladys J. Wilson, R.N., 9 Pine St., New Haven, Conn., Supervisor, Nursing Bureau, New Haven Dept. of Health
 Pauline Yabolnitsky, Peace River Health Unit, Pouce Coupe, B. C., Canada, Supervisor

Epidemiology Section

- Thomas G. DiBrizzi, M.D., 88 Garfield, Brooklyn 15, N. Y., Physician
 Daniel H. Fillmore, 7237 Summerdale Ave., Chicago 31, Ill., P.A. Sanitarian (R), U.S.P.H.S.; Director, Statistical Section, Chicago Venereal Disease Control Program
 Antonio Galvez Gomez, M.D., Escobar 570 (Bajos), Habana, Cuba, Jefe del Negociado de Desinfeccion y Presidente de la Comision de Clausuras de la Jefatura Local de Salubridad de La Habana
 Harris W. Hantman, D.V.M., 56 Norwood Av., Brooklyn, N. Y., Veterinarian
 Vicente Lago Pereda, M.D., Calle C 309, entre Fuentes y Lanuza, Reparto Almendares,

Marianao, Cuba, Jefe Local de Salubridad de La Habana
 Candido de Oliveira e Silva, M.D., Rua Barroso 227 N., Teresina-Pi, Brazil, S. A., Chief of Service of Control of Leprosy, Dept. of Health
 Emilio Soudy Castro, M.D., Hospital San Camilo, San Felipe, Chile, S. A., Asst. to Jefatura Sanitaria Provincial of the Province of Aconcagua
 William C. Spring, Jr., M.D., 2A Notre Dame St., Glens Falls, N. Y., Apprentice Epidemiologist, State Dept. of Health

School Health Section

Thelma S. Cline, R.N., 811 South Euclid Ave., Oak Park, Ill., Asst. Supervisor, Cook County Public Health Unit
 Marjorie McGrath, 207 Kingston Court, LaCrosse, Wis., Director of Student Health, State Teachers College
 Nathan E. Rudd, 440 Lenox Rd., Brooklyn 3, N. Y., District Health Education Counselor, Board of Education

Dental Health Section

Stephen P. Mallett, D.M.D., 358 Commonwealth Ave., Boston, Mass., Oral Surgeon, Boston City Hospital
 Zachary M. Stadt, D.M.D., 333 E. 17th St., New York 3, N. Y., Dentist
 Laurence E. Totten, D.M.D., 600 W. 168th St., New York, N. Y., Student, Columbia University, DeLamar Institute of Public Health

Unaffiliated

Flora B. Chisholm, M.A., 413 W. 148th St., New York, N. Y., Health Secretary, National Health Program
 V. Vembu Iyer, 13 Gordhan Niwas, Matunga, Bombay 19, India, Interested citizen
 Stephen C. Newitt, 7504 St. Charles Ave., New Orleans, La., Director, Division of Administrative Services, State Dept. of Health
 Morris Shiffman, D.V.M., M.P.H., 1416 Walton Ave., New York, N. Y., Quality Control Director, General Ice Cream Corp.
 Edgar G. Smeltzer, Jr., M.A., 87 Meadowbrook Rd., Hempstead, N. Y., Field Secy., Nassau County Tuberculosis and Public Health Assn.

DECEASED MEMBERS

Mrs. Ernestine Consigny, San Francisco, Calif., Elected Member 1931, Public Health Nursing Section
 William R. Martin, M.D., Charlotte County, Va., Elected Member 1943, Health Officers Section
 Horace Newhart, M.D., Minneapolis, Minn., Elected Member 1930, Maternal and Child Health Section
 Maurice H. Rees, Ph.D., M.D., Denver, Colo., Elected Member 1938, Public Health Education Section
 Sister Zoe Schieswohl, R.N., Carville, La., Elected Member 1937, Public Health Nursing Section

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing Officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y.

POSITIONS AVAILABLE

(Supplemental to list in January Journal)

Sanitary Engineer Wanted, City of Dallas, to be associated with public health department. Salary range \$171-\$270, starting salary depending on experience. Permanent position under civil service with participation in retirement plan. Make application to Civil Service Board, 309 City Hall, Dallas 1, Texas.

Wanted: Bacteriologist with B.S. or B.A. degree and 1 year training in public health bacteriology and serology to work in State Public Health Laboratory. Salary \$1,800 to \$2,280. Apply State Department of Health, Box 1877, Richmond, Va.

Territorial Department of Health—Juneau, Alaska—wants public health staff nurses. Minimum salary \$245 South-eastern, \$281.75 Interior. Minimum qualifications necessary: year of public health in school of nursing approved by N.O.P.H.N. and two years' experience, one under qualified supervision, preferably in V.N.A. or rural public health. Vacation one month, 14 days sick leave, 38 hour week. Apply directly to Director, Division of Public Health Nursing, Box 1931, Juneau, Alaska.

Sanitarians wanted: Salary range \$265-\$300 month. Possibility of advancement to higher classification. Minimum requirements 2 years' college work with courses in the sciences related to public health or approximately equivalent experience in field of environmental sanitation. Three months' course in public health is obligatory. Write Alaska Merit System, Box 201, Juneau, Alaska.

Health Education Consultant wanted: Salary \$300-\$345 month. Minimum requirements college degree and 1 year graduate work in public health. Experience: 1 year full-time paid employment in any of the fields of public health education. Write Alaska Merit System, Box 201, Juneau, Alaska.

Positions Available in Delaware: 2 County Health Officers, Director Tuberculosis Control, Director Venereal Dis-

ease Control, Physical Therapist, Occupational Therapist, Medical Social Worker. Experience and advanced training in public health essential in medical positions. For information write to Dr. Edwin Cameron, State Health Officer, Dover, Del.

Wanted: Medical Director, Municipal Tuberculosis Hospital, bed capacity 115. One with knowledge of surgery preferred. Permanent, full-time. Salary \$4,200 with full maintenance. Apply Box 583, Fall River, Mass.

Wanted: Medical officers needed for several openings in California, physicians to direct maternal and child health programs or venereal disease control work, and to assist local health officers. Requires license to practise in California. Salary \$4,800 year. Also opening for District Maternal and Child Health Medical Officer with training in pediatrics or obstetrics and public health. License to practise in California required. Salary \$4,800 year. Apply to State Department of Public Health, Room 612, Phelan Building, 760 Market Street, San Francisco 2, Calif.

Wanted: Physician trained in tuberculosis to assume permanent control of Tuberculosis Division of Health Department of Eastern city of 185,000. Applicant please state salary expected. Apply Box H, A.P.H.A.

Wanted: In City of Hartford, Conn., physician trained in venereal diseases to assume permanent administrative control of Venereal Diseases Division of the Health Department. Applicant please state salary expected. Apply Dept. of Health, Hartford, Conn.

Wanted: Health Educator. Entrance salary \$3,240. Top salary \$3,780 per annum; Epidemiologist and Registrar of Vital Statistics, M.D. with experience in epidemiology, entrance salary \$4,500, top salary \$5,000, plus, per annum; Staff Physician for health districts, qualification M.D., entrance salary \$3,158, top salary

\$3,879 per annum. Apply Commissioner of Health, City Hall, Cincinnati 2, Ohio.

Wanted: Executive Secretary for Hawaii Territorial Society for Mental Hygiene. New position. Salary \$350 month, advancement dependent on growth of Society and its work. Duties to guide, stimulate, and promote development of integrated program for the Society, now 3 years old. Major activities, education, coordination, publicity. Requirements, training and experience in psychiatric social work with demonstrated ability in public relations pre-

ferred. Will also consider candidates with training and successful experience in community organization. Selection to be made on basis of unassembled examination, including submission of short thesis on pertinent subject. For particulars write to the Society, clipper mail, attention Miss Vivian Johnson, Mabel Smythe Bldg., Honolulu, T. H.

Physical Therapy Technician for New Hampshire Department of Public Health. Apply to Merit System Council, State House, Concord, N. H.

POSITIONS WANTED

Senior Bacteriologist, 11 years' experience, 4½ years as U. S. Army laboratory officer with experience in dysentery and malaria and practical work in war bacteriology, tropical diseases, etc., seeks position anywhere in the U. S. L-480

Bacteriologist, woman, B.S. 1941, 5½ years' laboratory experience, hospital and public health, seeks position in or near New York City. Prefer desk position such as technical literature research, abstracting, etc. Also interested in laboratory work. L-481

Statistician and registrar of vital statistics for past four years in large city wishes to make a change. S-461

Graduate veterinarian, age 30, V.M.D. University of Pennsylvania, seeks position with city or state health department. Over 3 years' experience in army meat and dairy inspection including plant sanitary inspection. Over 6 years' experience in animal diseases and veterinary pathology. M-462

Sanitary Engineer, 5½ years' operational experience city sewage plant, nearly 4 years Captain in Sanitary Corps, U. S. Army, seeks position as sanitary engineer in Eastern U. S. E-488

Bacteriologist: M.A., Johns Hopkins, seeks position in Medical College or State Public Health Laboratory. Broad experience. L-482

EMPLOYMENT AND PLACEMENT SERVICE

The American Public Health Association announces an expansion of the Employment Service which has become a Counseling and Placement Service for public health workers and employers. This project which is primarily for the service of veterans has been made possible through the cooperation of the United States Public Health Service.

Counseling and guidance services for the various public health specialties are available to candidates through well trained staff consultants. Besides this function the Counseling and Placement Service establishes lines of contact between employers and candidates. It thus serves as a clearing house without recommending or sponsoring candidates or positions.

The facilities of the employment page are open to members free of charge.

Opportunities Wanted

Public health specialist expecting early discharge after four years with Army; degrees Eastern schools including certificate in public health from Johns Hopkins; ten years' successful administrative experience in public health; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Bacteriologist, now director of department, small college, is available for appointment; A.B., M.A., and Ph.D. degrees; seven years' teaching experience limited to Bacteriology and Immunology; recommended as a capable organizer; excellent teacher; for further information covering qualifications including bibliography, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Health educator is available; A.B. degree eastern school; graduate training in public health; in charge department of public health education in municipal health department, eight years; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Young physician well qualified as health educator; B.S., M.D. and master of health degrees; several years, director of university health service where he has carried a rather heavy teaching load; recommended as an exceptionally fine teacher, clear thinker about problems of education and student welfare, able to stimulate students to high degree of activity; for further information please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

NEWS FROM THE FIELD

DANGER OF MALARIA EPIDEMIC

STEADILY DECREASING

Risk of introduction of an epidemic of malaria by returning soldiers from overseas is continually decreasing, according to a statement by Major General Norman T. Kirk, Surgeon General of the Army.

The situation is reflected in the rate of admissions of malarious cases in hospitals in this country which reached a peak of 6,000 cases in February, 1945, and has been following a declining curve since that time, General Kirk said.

It is expected that the rate will continue to go down because a large proportion of the personnel of divisions heavily seeded with malaria in the early stages of the war already have been returned to this country.

At one time this disease was incapacitating about ten times more American soldiers than Japanese implements of war. The progress of the war in the Pacific in the early stages was seriously impeded until a special malaria control organization was established which helped bring this hazard under control, principally by anti-mosquito measures and atabrine.

During this high incidence of malaria in the Pacific there was concern that epidemics might develop in this country with the return of soldiers who had been infected. Since atabrine is not a cure but only a suppressive in most types of malaria, it was feared that returned soldiers who had stopped taking atabrine would suffer relapses which would lead to the spread of the disease here.

Lt. Colonel O. R. McCoy, Medical Corps, Chief of the Tropical Disease Control Division in the Preventive Medicine Service of the Surgeon Gen-

eral's Office, issued a statement in the fall of 1943 that, with proper precautions, there should be little danger of any serious epidemic of malaria in this country due to returning servicemen. Developments since that time have shown that the incidence of malaria among civilians in this country has not increased.

As men returned from overseas service during the latter part of 1943, the number of admissions to hospitals in the United States began to rise, bringing the total for the year to 5,075. Practically all of these cases represented relapses of malaria infections acquired overseas. In 1944 more than five times as many such cases were recorded, a total of 28,150. In the first six months of 1945 there were 30,420 such admissions. Since February, 1945, the curve has taken an abrupt downward turn that has steadily continued until the number of such cases is approaching the low level of the early part of 1943.

Colonel McCoy explained that in the majority of cases the disease has run its course after a man has suffered a few relapses, and no permanent damage has been done. Experience with the Pacific type of vivax malaria indicates that in 1,000 cases about one-third will have only one relapse. Only about 40 out of a thousand will suffer ten relapses, and only about one in a thousand will have as many as 20 attacks. The relapses are less severe as time goes on.

If a soldier who suffers a relapse of malaria is given proper treatment, the symptoms will be rapidly relieved and progress of the disease will be quickly suppressed, according to Colonel McCoy.

There is no permanent damage and only brief incapacitation results if

prompt and efficient action is taken. Fear of the disease due to lack of information can cause more harm than malaria itself.

The type of malaria of greatest military significance to American troops is vivax or benign tertian malaria, which is rarely a serious disease. About 90 per cent of Army cases are of this type. A man taking the necessary small doses of atabrine who has been infected with malaria can continue his arduous duties without suffering any symptoms. When the infected soldier stops taking atabrine the usual symptoms, chills, fever, headache and nausea, may appear. Atabrine does not always completely cure benign malaria.

Another type—malignant tertian malaria—which has been of concern to American troops can prove fatal if prompt and proper treatment is not given. Since this type can be completely cured by atabrine, it has not been so much of a problem as the benign type.

During a relapse a man may suffer loss of weight and anemia, but this can be corrected in a comparatively short time by rest, proper diet and, in some cases, a tonic. Complete recovery usually takes place before another relapse. The effects are not cumulative in the cases where individuals suffer a large number of relapses.

The yellow color the skin takes on as a result of taking atabrine gives concern to many victims of this disease. This is not due to jaundice or any malfunctioning of the body, but is caused by the yellow color of atabrine which is deposited in the skin. It will disappear a few weeks after the soldier stops taking atabrine.

Malaria has been a disabling disease in this war—it has been by far the major medical problem encountered by the Army overseas, but it has rarely been fatal. In the few cases of death, malaria has usually been associated

with other diseases and with circumstances which caused delay or inadequate treatment, according to Army records.

SOUTH AFRICA TO CREATE ITS WAR MEMORIAL IN HEALTH

A dispatch on January 9 from Pretoria, South Africa, carries a statement of the Ministry of Health that South Africa's national war memorial will be a healthy people. According to the statement, a nation-wide health appeal is to be launched, including plans for the establishment of an institute of nutritional research, health education, and scholarships to train a staff, particularly a non-European staff, for the national health service.

GENERAL KELSER APPOINTED DEAN OF VETERINARY MEDICINE AT PENNSYLVANIA

Brigadier General Raymond A. Kelser, who for the last 8 years has been Chief of the Veterinary Division of the Office of the Surgeon General, U. S. Army, Washington, has been appointed Dean of the School of Veterinary Medicine at the University of Pennsylvania at Philadelphia. He is expected to resume his duties shortly. General Kelser is the Chairman of the Standard Methods Committee on Biology of the Laboratory Animal of the Laboratory Section, A.P.H.A.

HARVARD APPOINTS GENERAL SIMMONS AS DEAN

President James B. Conant of Harvard University on January 9 announced the appointment of Brigadier General James S. Simmons, U.S.A., Chief of the Preventive Medicine Service, Office of the Surgeon General, Washington, as Dean of the Harvard School of Public Health, Boston, effective about July 1, 1946. General Simmons, who was born in 1890, received his medical degree at the Uni-

versity of Pennsylvania in 1915, a Ph.D. from George Washington University Medical School in 1934, and the doctorate in public health from the Harvard School of Public Health in 1939. He entered the Army Medical Corps in 1916, served as chief of laboratory services in various U. S. Army hospitals, and commanding officer of departmental laboratories and, from 1924 to 1928 was chief of the bacteriological department of the Army Medical, Dental and Veterinary Schools. He has lectured and written extensively on experimental bacteriology, preventive medicine, and tropical medicine. He has recently received the Distinguished Service Medal for his military work, and in 1943 was awarded the Sedgwick Memorial Medal by the American Public Health Association. He received the Sternberg Medal in 1940. General Simmons is President of the American Academy of Tropical Medicine and of the American Society of Tropical Medicine.

James Stevens Simmons

President Conant also announced the reorganization of the Harvard School of Public Health which will give it co-equal status in the University with the

Harvard Medical School and other professional divisions. He announced that the Rockefeller Foundation has granted a million dollars for the expenses of the school for ten years, beginning July 1, 1946, and that the University has set aside an additional sum of \$750,000 as an endowment to supplement the present endowment fund. In addition to its present building on Shattuck Street, Boston, the Harvard School of Public Health will occupy the Harvard-owned Collis P. Huntington Memorial Hospital nearby which will be remodeled, giving the school an additional 40,000 square feet of floor space.

CAPTAIN G. W. LARIMORE RECEIVES LEGION OF MERIT

The War Department has announced the award of the Legion of Merit to Capt. Granville W. Larimore, Chief of the Health Education Branch, Medical Intelligence and Health Education Division, Office of the Surgeon General, U. S. Army, for his outstanding educational work.

The award was made by Major General Norman T. Kirk, Surgeon General of the Army, in line with the War Department's policy of giving personal recognition to individuals who help provide what Secretary of War Patterson recently described as the best medical care any army ever received in any war.

DR. PETTY APPOINTED NEBRASKA STATE DIRECTOR OF PUBLIC HEALTH

Governor Dwight Griswold of Nebraska announced in December the appointment of Wallace S. Petty, M.D., of Lincoln, as State Director of Public Health, succeeding C. A. Selby, M.D., resigned.

Dr. Petty received his medical degree in 1908 and has been in public health work since 1925 when he joined the Missouri State Department of Health. He served for ten years with

the Iowa State Health Department, resigning in 1940 to attend the University of Minnesota where he obtained a Master's degree in public health work. Dr. Petty joined the Nebraska State Department of Health in January, 1942, and served for several months as Acting Director. He is a member of the A.P.H.A. Committee on Administrative Practice, representing the Health Officers Section.

AMERICAN MEDICAL ASSOCIATION
APPOINTS GENERAL LULL
TO STAFF

The appointment of Major General George F. Lull of Scranton, Pa., War Department Deputy Surgeon General, as Assistant Secretary and General Manager of the American Medical Association, Chicago, has been announced. General Lull has retired at his own request after more than thirty-three years in the regular Army. He served as Chief of Personnel for the Army Medical Corps from 1940 to 1943, when he became Deputy Surgeon General and was in charge of recruiting civilian physicians as reserve officers. The appointment was effective with the first of the year.

INDIANA SETS UP DIVISION OF
GERIATRICS

L. E. Burney, M.D., State Health Commissioner of Health, Indianapolis, Ind., announces the creation of a new division in the Indiana State Board of Health to be known as the Division of Adult Hygiene and Geriatrics. The last Legislature provided for this new program and set forth the purpose in the following language: "The State Board of Health shall provide facilities and personnel for research, investigation, and dissemination of knowledge to the public concerning the health of persons of middle and advanced age and diseases common thereto, and also concerning dental pub-

lic health. The State Board of Health is hereby vested with discretion for providing means and methods for research, investigation, and dissemination of knowledge, and may make, adopt, and promulgate rules and regulations for establishing proper facilities and personnel and to carry on the work described in this section."

In creating this new division certain principles and objectives have been formed, and a program designed to accomplish these objectives is now being planned. The objectives, briefly stated, are as follows:

1. To study the factors of life that are related to senescence and senility and the diseases and disabilities associated with advancing years.
2. To plan for the care and well-being of those whose advancing years and experience entitle them to the best protection and support that medical knowledge and adequate care can provide.
3. To inform the public concerning diseases and disabilities of advancing age, and to stimulate the interest of the medical profession in diseases of age.
4. To cooperate with and assist both the lay public and professional groups in a full appreciation of the economic, social and cultural value and usefulness of men and women who by reason of age and experience constitute a most important group of our population.
5. To be interested in laws, rules and regulations, conditions and requirements as may affect the well-being and usefulness of men and women in advancing years, and to seek improvement of such laws, rules and regulations, conditions and requirements as may affect the elderly adversely.

The magnitude of the problem of advancing years, according to Dr. Burney, is indicated by recent United States Census reports. In 1900 approximately 18 per cent of the population of the United States had reached the age of 45 and over. The census of 1940 showed that 27 per cent of the total population were 45 and over. The number of men and women in the State of Indiana who today have at-

tained the age of 60 is in excess of 350,000. The number in this age group in continental United States is estimated above 13 million. Within the last census decade, 1930 to 1940, there was an increase in the number of persons of age 65 and over to 35 per cent, while in contrast the total population increase was but 7.2 per cent in the same period.

The Division of Adult Hygiene and Geriatrics is under the directorship of William F. King, M.D. The work of this division in carrying out its objectives will be watched with much interest, since this is said to be the first official activity by any state in this new field of public health endeavor.

DR. JOHN WHEELER APPOINTED NEW HAMPSHIRE STATE HEALTH OFFICER

John S. Wheeler, M.D., M.P.H., of Concord, N. H., has been appointed State Health Officer to succeed Alfred L. Frechette, M.D., M.P.H., who has resigned to become Health Officer of Brookline, Mass.

Dr. Wheeler, who is a graduate in medicine of Boston University Medical School in 1930, has his degree in public health from Johns Hopkins in 1938 and served for several years as epidemiologist and director of the Division of Local Health Work in New Hampshire, beginning in 1937.

NATIONAL CONFERENCE FOR COOPERATION IN HEALTH EDUCATION MEETS IN NEW YORK

A two day session of the National Conference for Cooperation in Health Education met in New York City December 29 and 30, and was well attended by representatives of various national agencies who came from as far west as California. Ira V. Hiscock, D.Sc., Professor of Public Health at Yale University School of Medicine, New Haven, represented the American Public Health Association.

The following officers were elected:

Chairman, Dr. John L. Bracken, Superintendent, Board of Education, Clayton, Mo., representing American Association of School Administrators

Vice Chairman, Bosse B. Randle, R.N., Mineola, N. Y., representing N.O.P.H.N.

Secretary, Vivian Drenckhan, New York, representing National Tuberculosis Association

Additional members of Executive Committee: W. W. Bauer, M.D., American Medical Association; Mayhew Derryberry, Ph.D., U. S. Public Health Service

CANADIAN PUBLIC HEALTH ASSOCIATION APPOINTS EXECUTIVE DIRECTOR

The Canadian Public Health Association, Toronto, has announced the appointment of J. H. Baillie, M.D., D.P.H., as Executive Director. Dr. Baillie is a graduate in medicine from the University of Toronto in 1938 and holds the Diploma in Public Health from Toronto in 1941. He has had experience in practice and has served in the Royal Canadian Air Force, where his services were recognized by a series of promotions. He recently has been in charge of hygiene and preventive medicine in the Directorate of Medical Services, Ottawa.

MASSACHUSETTS DENTAL SURVEY

The Dental Bureau of the Massachusetts Department of Public Health, in preparation for conducting a research program in the control of dental caries, is making a survey to determine the incidence of caries among children by age groups and to determine the availability of sufficient dentists to cope with the existing problem.

The fluoride content of all public water supplies in the state has already been determined and in only one town, Farnumsville, was as much as 1 part per million of sodium fluoride (1.3 p.p.m.) found. In all other public water supplies the amount of sodium fluoride was near 0.2 p.p.m.

These data will be used as the basis for the proposed study which will investigate the control of dental caries by utilizing fluorides in the following ways: in public water supplies, in prophylactic pastes and mouth washes, in pastilles and lozenges, in pills, and in topical applications.

DR. PERKINS APPOINTED NEW YORK
STATE DEPUTY COMMISSIONER

Edward S. Godfrey, Jr., M.D., New York State Commissioner of Health, Albany, has announced the appointment as Deputy Commissioner of Health of James E. Perkins, M.D., Dr.P.H., who has been associated with the department for the past 12 years as epidemiologist, as District State Health Officer, and more recently as Director of the Division of Communicable Diseases. Dr. Perkins is a graduate in medicine of the University of Minnesota and in public health from Johns Hopkins School of Hygiene and Public Health. He is Associate Professor of Public Health and Preventive Medicine at the Albany Medical College, and serves as Associate Editor of the *American Journal of Public Health*, as well as Secretary of the Epidemiology Section, A.P.H.A. He recently was appointed Chairman of the A.P.H.A. Subcommittee for the Evaluation of Methods to Control Air-borne Infection. Dr. Perkins served for several months during 1945 in Italy as a commissioned officer of the U. S. Public Health Service, making a survey of the effect of the war on the Italian civilian population with regard to nutrition and communicable diseases.

DR. SUMNER MILLER OF PEORIA DIES

Dr. Sumner M. Miller of Peoria, Ill., full-time Health Officer of Peoria since 1938, died December 14 at the age of 72, after a long illness.

Since 1906 Dr. Miller had been actively identified with community

health services in Peoria. He was President for 17 years of the Peoria Tuberculosis Society and was the founder and first President of the Peoria County Chapter of the American Red Cross. He was a Fellow of the American Public Health Association and a founder and President of the Illinois Public Health Association.

Following a reorganization of the Peoria Health Department in 1938, Dr. Miller left the active practice of medicine and developed the department so that it won recognition in 1943 and 1944 of the cities in its population group in the inter-chamber Health Conservation Honor Roll.

DR. DON W. GUDAKUNST DIES

Don W. Gudakunst, M.D., Dr.P.H., Medical Director of the National Foundation for Infantile Paralysis for the last six years, died January 20 from a heart attack in Chicago at the age of 51. Dr. Gudakunst, who was a native of Ohio, held a medical degree in 1919 from the University of Michigan. Dr. Gudakunst had served since 1924 in various public health capacities, beginning with the School Health Service in Detroit, where he was also Deputy Commissioner of Health and later, in 1938-1939, Michigan State Commissioner of Health. He served for a time before 1940 in the Reserve of the U. S. Public Health Service and since that time has been Medical Director of the National Foundation for Infantile Paralysis, New York, expanding the program of research and medical care. He was a Fellow of the American Public Health Association and Chairman of the Committee on Eligibility at the time of his death.

AMERICAN WATER WORKS ASSOCIATION
1946 CONFERENCE

The American Water Works Association 1946 Conference will be held in St. Louis, Mo., May 6-10.

PERSONALS

Central States

CLAYTON C. BENJAMIN, M.D.,† Manistee, Mich., has resigned as Health Officer of Mason County to accept a similar position for the city of Port Huron, Mich.

ROBERT E. FLOOD, M.D., Northport, Mich., has been appointed Director of the Michigan District Number 7 Health Unit to succeed Dr. MADELINE M. DONNELLY, Gladwin.

CHANGES IN HEALTH PERSONNEL IN ILLINOIS:

LESLIE W. KNOTT, M.D., M.P.H.,† on leave of absence from the U. S. Public Health Service, was appointed Medical Administrative Assistant, Illinois Department of Public Health, effective November 15. He has been replaced in the Division of Venereal Disease Control by Dr. CHARLES H. MILLER.

JEAN CHRISTOPHER, M.S.P.H.,* has been appointed Acting Chief of the Division of Public Health Education, Illinois Department of Public Health, effective November 1.

O. K. SAGEN, Ph.D.,† has been appointed Chief, Division of Vital Statistics and Records, effective December 1.

MAJOR CLARENCE W. KLASSEN* resumed his duties as Chief of the Division of Sanitary Engineering, Illinois Department of Public Health, effective October 12.

JAMES W. CHAPMAN, M.D., M.P.H.,* succeeded Dr. SIDNEY I. FRANKLIN as Health Officer of the DuPage County Health Department, Villa Park, Ill., effective November 1. Dr. Chapman was formerly Health Officer of the McMinn County Health Department, Athens, Tenn.

NEWTON W. LARKUM, M.D.,* after more than 4½ years on active duty

in the Army, during which period he served for a while as Chief of the Division of Bacteriology at the Army Medical School and later as Chief of Laboratory Service, 100th General Hospital in England and France, has been released. Before the war he was connected with the Michigan Department of Health. At present Dr. Larkum is Medical Director for the Ames Company of Elkhart, Ind.

PAUL A. LINQUIST, M.D.,† Surgeon (R), USPHS, has been released to inactive status in the service and has been appointed City-County Director of Health for Kansas City and Wyandotte County, Kan.

CHARLES M. MCGILL, M.D., of the U. S. Public Health Service, has been named Chief of the Industrial Hygiene Division of the Ohio State Department of Health.

CHANGES IN HEALTH PERSONNEL IN NORTH DAKOTA:

LT. COL. LLOYD K. CLARK,* after nearly 5 years of army service, returned to his former position as Director of the Division of Sanitary Engineering. He replaces JEROME H. SVORE, Senior Sanitary Engineer in the department, who had been Acting Director.

DR. WILLIAM M. SMITH,* Rome, N. Y., has been named Director of the Division of Preventable Diseases. DR. CAMPANA had been serving as Acting Director of this Division.

ROBERT R. KLING, M.D., Bismarck, was chosen Tuberculosis Consultant in the Division of Preventable Diseases.

CARL A. SCHERER, M.D.,† Duluth, Minn., has been appointed Health Officer of the Sutter-Yuba Bi-County Health Unit, effective September 5. Before going to California, Dr. Scherer was for 10 years Health

* Fellow A.P.H.A.

† Member, A.P.H.A.

Officer of St. Louis County, Minn., and Director of Rural Health Unit 4 of the Minnesota State Board of Health.

C. A. SELBY, M.D.,† resigned as State Health Director in Nebraska, effective January 31, as announced in December by GOVERNOR DWIGHT GRISWOLD. Dr. Selby, who is a resident of North Platte, Neb., has served since November, 1942.

CHARLES F. WAGG, M.D., Executive Secretary of the former Michigan State Hospital Commission, has been named Acting Executive Officer of the new Michigan Department of Mental Health, pending formulation and adoption of a permanent organizational structure. The new department, which was set up by the 1945 legislature, is now attempting to find a satisfactory candidate for the position of Director of Mental Health.

WILLIAM D. WEIS, M.D.,† has been selected by the Board of County Commissioners of Lake County, Ind., for the fourth time to serve a 4 year term as County Health Commissioner.

Eastern States

LT. COL. WALTER M. CULLEY, SN.C.,† for the past 4 years Chief Sanitary Engineer of the Second Service Command and stationed at Governors Island, has become associated with J. LLOYD BARRON* as a Sanitary Engineer for the National Biscuit Company with offices in New York City. Mr. Culley was formerly engineer of the Chester, Pa., Municipal Authority Water Service.

ALFRED L. FRECHETTE, M.D.,† Secretary and State Health Officer of the New Hampshire State Board of Health, Concord, has resigned to become Health Officer of Brookline, Mass. MAJOR JOHN S. WHEELER, formerly Deputy Health Officer in

New Hampshire, has been appointed Health Officer as of December 1.

COLONEL WILLIAM A. HARDENBERGH, SN., A.U.S., who has been Director of the Sanitation and Sanitary Engineering Division, Preventive Medicine Service, Office of the Surgeon General, U. S. Army, Washington, has returned to civilian life, resuming his position as Editor of the *Public Works Magazine*, New York City.

HOLLIS S. INGRAHAM, M.D., M.P.H.,* has been appointed provisionally as Director of the New York State Health Department's Division of Communicable Diseases, succeeding JAMES E. PERKINS, M.D.,* Deputy State Health Commissioner. Dr. Ingraham has been associated with the Health Department for 12 years with the exception of the past 3½ years spent in the Navy.

CHANGES IN HEALTH OFFICERS IN NEW YORK STATE:

PAUL B. BROOKS, M.D.,* Deputy State Health Commissioner, has announced his retirement effective December 31. Dr. Brooks was appointed Sanitary Supervisor on March 1, 1915. Later he served as Director of the Division of Communicable Diseases, Assistant to the Director of the Division of Laboratories and Research, and was appointed Deputy State Health Commissioner by DR. NICOLL on July 1, 1923. He has continued to serve in this capacity since that time.

SAMUEL HYMAN, M.D.,* Utica District State Health Officer, resigned October 15 and is now in Chicago.

GEORGE JAMES, M.D.,† ERNEST S. KINSEY, M.D.,† and DONALD C. TULLOCH, M.D.,† were appointed Assistant District Health Officers

* Fellow A.P.H.A.

† Member, A.P.H.A.

effective June 1, 1945, and were assigned to the Middletown, Binghamton and Albany district offices respectively.

KENNETH S. LANDAUER, M.D.,† was appointed Director of the New York State Reconstruction Home effective November 1, 1945.

LOUIS PLATT, M.D.,† Assistant District Health Officer in the Rochester District, resigned effective October 16, 1945.

W. C. SPRING, M.D., Jefferson, O., and C. M. STEWARD, M.D., Norwich, N. Y., were appointed Apprentice Epidemiologists effective November 16 and December 1, respectively.

THOMAS C. STOWELL,† Assistant Director of the Division of Public Health Education is on leave of absence to serve as Director of the Radio Bureau of the Department of Commerce.

MATTIE WASHBURN, R.N., Assistant Director of the Division of Public Health Nursing, has announced her retirement effective December 31. Miss Washburn was first appointed to the position of Supervising Nurse on August 9, 1920. She was appointed Assistant Director of the Division of Public Health Nursing on March 1, 1933.

ROBERT S. WESTPHAL, M.D.,* formerly Assistant Director of the Division of Syphilis Control, was appointed to the position of District State Health Officer and assigned to the Rochester District effective June 4, 1945.

RUTH RIVES, R.N.,† former District Supervising Nurse at Glens Falls, N. Y., has been appointed Assistant Director of the Division of Public Health Nursing, effective January 1.

DAVID R. SALMON has been appointed Executive Director of the National

Council on Rehabilitation, New York, N. Y.

COLONEL JAMES A. TOBEY, SN.C.,* returned to his home in Rye, N. Y., on December 24 after 2 years and 8 months overseas. During this period, he participated in 7 combat operations and served with the U. S. military Government in North Africa, Sicily, Italy, England, France, and Germany. For 7 months prior to his return, Colonel Tobey was Deputy Military Governor and Chief of the Department of the Interior in Wurttemberg-Baden. In this area of over three million German population, he had charge of public health, public welfare, public safety, public works, and administration and local government. He has received three decorations from the French Republic.

G. HAROLD WARNOCK, M.D.,* has returned from military service to his position as epidemiologist with the Nassau County Dept. of Health, Mineola, N. Y.

Southern States

THOMAS MALCOLM BLAKE, M.D., has been named Health Officer of Winston County, Ala., to succeed Dr. HUGH C. McREE,† Hamilton, who resigned September 1. Dr. MARVIN S. WHITE, Hamilton, has been named to a similar position in Marion County also to succeed Dr. McRee. SAMUEL R. DAMON, PH.D.,† who has been Director of Laboratories with the Alabama State Department of Health for several years, and formerly Associate Professor of Bacteriology at Johns Hopkins School of Hygiene and Public Health, Baltimore, has resigned to become on January 1 Director of the Bureau of Laboratories of the Indiana State Board of Health, Indianapolis.

HOWARD W. ENNES, JR.,† Lieut. H(S), USNR, was commended for services

* Fellow A.P.H.A.

† Member, A.P.H.A.

during the war in the Venereal Disease Control Section, Bureau of Medicine and Surgery, Navy Department, by VICE-ADMIRAL ROSS T. MCINTIRE (MC), USN, Surgeon General of the Navy, by direction of the Secretary of the Navy. Lieut. Ennes is serving as Assistant to the Officer in Charge of the Venereal Disease Control Section.

RICHARD J. PLUNKETT, Major, MC, AUS,† has been appointed Field Consultant for the Division on Health and Sanitation, Institute of Inter-American Affairs. The appointment is part of the Institute's plan to mold wartime coöperative advances in hemisphere health into permanent peacetime channels. Major Plunkett has already started a lengthy inspection and consulting tour which will take him to Bolivia, Chile, Uruguay, Peru, Ecuador, Colombia and the republics of Central America, according to an announcement.

WILLIAM P. SCARLETT, M.D.,† Morrilton, Ark., formerly Health Officer of Wichita, Tex., has been named Health Officer of Little Rock, Ark.

Western States

C. ARTHUR ELDEN, M.D.,† was appointed Obstetric Consultant with the Washington State Department of Health on November 15, and will work in the Maternal and Child Health and Crippled Children's Section. Dr. Elden had previously been Assistant Professor of Obstetrics and Gynecology at the University of Rochester Medical School for 13 years at Rochester, N. Y., and also was in private practice during that time.

HELEN G. SCHWARTZ resigned from her position as Assistant Director in charge of the Western Area, Division of Nurse Education, U. S. Public Health Service, as of January 1. She has gone to Minnesota to take up her new position as Nurse Education

Advisor on the Minnesota State Board of Nurse Examiners.

GEORGE M. SHAHAN † has resigned his position as Assistant Executive Secretary and Director of Public Relations with the Los Angeles Tuberculosis and Health Association, Los Angeles, Calif., and has been appointed Executive Secretary of the Washington Tuberculosis Association with headquarters in Seattle.

IRVIN R. VAUGHN, Seattle, Wash.,† who was appointed as Acting State Registrar with the State Department of Health on November 26, will be the Acting Head of the Public Health Statistics Section. Mr. Vaughn was formerly Director of Vital Statistics for the State Board of Health of South Dakota.

Foreign

G. HOWARD GOWEN, M.D. (Lt. Col., MC, AUS),* has returned to the University of Michigan School of Public Health after 31 months overseas in North Africa, Italy, France and Germany where he was Director of Laboratories, Epidemiologist and head of the Preventive Medicine Section of the 7th Army for 12 months.

LT. COL. WILLIAM REINER-DEUTSCH, SN.C.,† lately Executive Officer of 191 General Hospital in Paris, has returned to New York City.

* Fellow A.P.H.A.

† Member, A.P.H.A.

The Place of Fertility Control in Public Health*

REGINE K. STIX, M.D.

New York, N. Y.

WITHIN the past fifteen years there has been growing recognition of the fact that the "birth control movement" is only a new aspect of an age-old attempt on the part of people to solve for themselves the problems of family size. Historical records show that, in addition to abortion and infanticide, crude methods of contraception have been used as a means of controlling fertility since 1500 B.C. or earlier.¹ There is increasing understanding of the close association between the problems of excess fertility and sterility and those of infant and maternal morbidity and mortality, and, as a result, a number of states and cities are including advice on fertility control in their maternal health programs. It seems timely, therefore, to review briefly the background of the public health aspects of the problem and to appraise what has been done in the field to date.

The results of population studies in the United States within the past fifteen years have revealed certain persistent

trends and differentials which bear directly on the rôle which public health may play in dealing with the problems of fertility. The approach is twofold: the prevention of disease associated with childbearing, where possible, and the more indirect effort to raise general standards of health by lowering excess population pressures and improving standards of living.

Clear-cut regional, rural-urban, and socio-economic differentials in fertility have characterized the population picture in the United States for the past century or more. They were still present in 1940, when the ratio of children to women was approximately 65 per cent higher in the predominantly rural East South Central states than in the highly industrialized Middle Atlantic region. For the country as a whole, fertility rates of white farm women were 120 per cent higher than those of women in cities of 500,000 and over, and there was a consistent decline in fertility with increasing size of community.^{2, 3}

Within each region there has also been a persistent inverse association be-

* Special Review Article, prepared at the request of the Editorial Board.

tween birth rates and socio-economic status. Birth rates have been highest in those groups with the lowest incomes and the least education, and lowest in the groups with the highest educational attainment and highest incomes. Within the last two decades, however, there has been a tendency for rates to remain relatively stable among groups with the highest socio-economic status, while still declining in the lower income and less educated groups. Thus, since 1930, fertility rates in the group with the highest economic status have been slightly higher than those in the next lower socio-economic group. This may presage the beginning of a change in the general trend which has persisted since the industrial revolution.⁴

Until Raymond Pearl published his study of the prevalence and effectiveness of the contraceptive efforts of a large group of women who came to hospitals in cities east of the Mississippi to bear children, it was generally believed that women in the lower economic levels were innately more fertile than those of higher economic status. There was much discussion of the effect of higher education and careers for women on their ability to bear children. Pearl's study presented for the first time scientific evidence that the observed differentials in birth rates were due, in major part if not entirely, to differences in the prevalence and effectiveness of contraception and abortion in the various socio-economic groups. Pregnancy rates when no contraception was used showed no significant differences from group to group. Pearl found a direct association between the prevalence and effectiveness of contraception and socio-economic class. Before the wife came to a hospital to have a baby, 78.3 per cent of the well-to-do and rich couples in his group had used contraception, but only 32.7 per cent of the poor couples had attempted contraceptive practice.⁵

Pearl's findings have been substantiated by later studies of selected samples of women who showed a special interest in controlling their fertility by attending birth control clinics or accepting special advice on contraception. Even before these women were given special advice on birth control techniques, differences in the prevalence and effectiveness of contraceptive practice were the main determinants in birth rate differentials within the groups studied. These studies of women who came to clinics for advice on contraception or who were given such advice by a nurse in their homes were made in four areas. The three clinic populations studied were a selected group of women from the Bronx, who attended the Birth Control Clinical Research Bureau in New York City, a group of patients of the Cincinnati (Ohio) Maternal Health Clinic, and a group who attended the Spartanburg (S. C.) Maternal Health Clinic. The field study was made in Logan County, W. Va.⁶⁻⁹

The women in Pearl's sample, being patients in maternity hospitals, constituted a select group with respect to overt fertility and could by definition include only those women who bore at least one child each during the period of study. The women in the other studies quoted, who sought or accepted special contraceptive advice, were probably highly fertile. Thus, until very recently, our knowledge of the prevalence and effectiveness of contraceptive practice has been limited to information about families with demonstrated fertility.

The first detailed study of a large population group, unselected with respect to overt fertility or a special interest in fertility control, was initiated in 1941. It was conducted in Indianapolis by the Committee on Social and Psychological Factors Affecting Fertility, and sponsored by the Milbank Memorial Fund, with grants from the

Carnegie Corporation of New York. To date, only the preliminary analyses of the material have been published, but unpublished data appear to substantiate the thesis that variation in the prevalence and effectiveness of contraceptive practice is probably the most important factor in the production of differentials in fertility in a group which is fairly representative of the white urban population of the United States.¹⁰

Materials for all the studies discussed above were secured by interviewing women* and ascertaining from them, in addition to basic data on age, date of marriage, etc., information concerning the date and type of termination and length of gestation of each pregnancy and the type of contraceptive practice, if any, which preceded it. The women were also asked whether contraceptive practice was deliberately interrupted in order to permit pregnancy to occur, and, if the pregnancy terminated in abortion, whether the abortion was spontaneous or induced. Information concerning morbidity associated with pregnancy was also collected. A mass of interesting data was secured, but for the purposes of this review, discussion will be limited to those data relating to contraceptive practice.

In all groups studied, the couples involved had used mainly the types of contraception generally available, rather than the occlusive feminine methods frequently advocated by physicians and in general use in birth control clinics. Those most commonly used in the rural South, as well as in large cities, were condoms, coitus interruptus and douches of various kinds. Pregnancy rates computed separately for experience with each type of contraceptive, and compared with those of the same groups of women when no contraception was used,

show that even without special instruction in approved techniques, the use of contraception reduced the risk of pregnancy considerably, depending on the type of contraception used and the regularity of its use.⁹⁻¹³

In each of the studies discussed, the method of computing pregnancy rates consisted in relating total reported experience without contraception to the number of pregnancies occurring during this experience, and in making a similar type of computation for experience with all contraceptives and with each separately. Time pregnant and prolonged absences of husband and wife were subtracted from the total experience, since during these periods the wife was presumably not exposed to the risk of pregnancy. Pregnancy rates were computed as pregnancies occurring in each hundred-person years' exposure to the risk of pregnancy. Experience of all couples in each category of contraceptive or non-contraceptive experience was pooled.^{14, 6, 9}

Certain findings were common to all the studies. Pregnancy rates during periods when no contraception was used showed no significant differences for different socio-economic groups, when the experience of women with known pelvic pathology was excluded from the total experience.⁵⁻⁷ There were regional differences in the total non-contraceptive rates observed in New York, Cincinnati, and the two southern groups, which were largely attributable to differences in the proportions of women in the four groups who were known to have serious pelvic pathology or other diseases which might interfere with fertility. Rates without contraception were highest in the New York group and lowest in the two southern rural groups studied.^{8, 9} Because of the wider and more effective use of contraception in the urban areas, however, pregnancy rates for all experience, with and without contraception, showed pre-

* In the Indianapolis study, schedules were secured from both husbands and wives.

TABLE 1

Mean Number of Months of Exposure per Pregnancy for the Non-contraceptive Experience of Four Groups of Women Prior to Clinic Attendance

Order of Pregnancy	White Patients of						Negro Patients of Spartanburg Maternal Health Clinic		
	Clinical Research Bureau (N. Y. C.)		Cincinnati Maternal Health Clinics		Spartanburg Maternal Health Clinic

All later pregnancies	3,883	341	20,357	1,583	20,862	1,228	18,667	1,283	

cisely the reverse differential, with the highest rates in Spartanburg and in Logan, and the lowest in New York City.

The average woman in the New York group conceived her first pregnancy 4 months after marriage, when no attempt was made to use birth control methods. In Cincinnati, and for both Negro and white women in Spartanburg, the average interval between marriage and the first conception was between 7 and 8 months.

After the first pregnancy, the rate of conception was lower, even when no attempt was made to control fertility, probably because of lactation and associated amenorrhea. The differences observed between the groups were in

the same direction as those observed for first pregnancies, but less marked (Table 1).

For those couples who practised contraception from marriage, the elapsed time between marriage and the first pregnancy was considerably longer than when no contraception was used, and the same was true of the exposure for later pregnancies as may be seen in Table 2.

The effectiveness of the contraception used varied considerably from group to group. For the New York women, the types of contraception used before clinic attendance reduced the risk of pregnancy by 79 per cent. In Cincinnati, the risk was reduced by 52 per cent; while in Spartanburg, the white women

TABLE 2

Mean Number of Months of Exposure per Pregnancy for the Experience with Contraceptives of Four Groups of Women Prior to Clinic Attendance

Order of Pregnancy	White Patients of			Negro Patients of Spartanburg Maternal Health Clinic				
	Clinical Research Bureau (N. Y. C.)	Cincinnati Maternal Health Clinics	Spartanburg Maternal Health Clinic					
	Mean Number of Months of Exposure per Pregnancy

	Exposure in Months and Number of Pregnancies							
	Exp. Mo.	No. Preg.	Exp. Mo.	No. Preg.	Exp. Mo.	No. Preg.	Exp. Mo.	No. Preg.
First pregnancies	5,085	174	4,330	254	934	50	248	22
All later pregnancies	63,838	1,459	73,655	3,379	13,656	484	3,493	170

had rates 47 per cent lower than were observed during the periods when no contraception was used, and the Negro women, rates 28 per cent lower. The effectiveness of untutored efforts at contraception noted in other studies ranged between 46 and 63 per cent.^{13, 9}

The practice of contraception in each case included all types of use, both regular and irregular, and it is obvious that couples in the rural areas, who had less access to contraceptive materials than those in the urban areas, not only used less effective contraceptives, but used them less regularly, because of more primitive living conditions.

Most of the couples who practised contraception from the time of marriage, as well as many others who started its use after the first or second pregnancy, interrupted its use for at least one "planned pregnancy." Twenty-two per cent of first pregnancies, 25 per cent of second pregnancies, and 20 per cent of third pregnancies in the New York group studied, resulted when the practice of contraception was deliberately interrupted in order to permit pregnancy to occur. Pregnancy rates for these conceptions were consistently and significantly higher than those of women in the same group who had never used contraception. Fifty-four per cent of these "planned pregnancies" were conceived within a month after the couples stopped using contraception, and 80 per cent of them within 3 months.⁶

Rates for "planned pregnancies" in the other groups studied were of the same order, but there was insufficient material for publication. Thus, there is no indication that the use of contraception, at least in the groups observed, impaired the fecundity of the users.

The professional contraceptive services offered these women were of three types. In New York, women came of their own accord to a voluntary agency—the Birth Control Clinical Research

Bureau—for advice about controlling fertility which appeared to them alarmingly high. Many of them had resorted to abortion to control the size of their families.⁶

In Cincinnati, the Maternal Health Clinic sponsored by the local Academy of Medicine advised mainly women referred for health reasons. They did not conceive as rapidly as the women in the New York group before they attempted contraception, but, because they used less contraception and used it less effectively, the average number of pregnancies per woman was greater. Some of them were referred because of illness contraindicating further pregnancy, and others because poor economic conditions and large families were already placing intolerable burdens upon them.

The Spartanburg Maternal Health Clinic, in the Spartanburg General Hospital, is one of the regularly operated clinics of the County Department of Health. It accepts only patients referred from other clinics in the General Hospital. Each record in the series studied contained a digest of the medical findings, a report of pelvic examination, and laboratory reports on vaginal and urethral smears, Wassermann and urinalysis. The series did not, of course, include women with sterilizing pathology, since such women would not have been referred for contraceptive advice.

Table 3 shows the distribution of cases by the main reason for advising contraception. Only 19 per cent of the white women and 16 per cent of the Negro women referred during the years 1935-1939 were referred for child-spacing only. The remainder were referred because of illness which made it inadvisable for them to become pregnant. More than 40 per cent were referred because of serious illness, such as tuberculosis, syphilis, heart disease, nephritis, or pellagra; an additional 30 per cent were referred because of

TABLE 3

Distribution of Reasons for Advising Contraception for Patients of the Spartanburg Maternal Health Clinic

<i>Main Reason for Advising Contraception</i>	<i>White Women</i>	<i>Negro Women</i>
Total Number of Women Advised *	532	455
	<i>Per cent Advised for Each Reason</i>	
Total	100.1	100.0
Child Spacing Only	19.0	16.3
Tuberculosis or Tuberculosis Contact	4.9	1.5
Syphilis or Syphilis Contact	4.5	25.1
Cardiac or Vascular Disease	4.7	6.8
Pyelitis, Nephritis, or Previous Toxemia	10.7	6.8

Diseases of Endocrine Origin †	3.4	2.2
Diseases of the Pelvis Other than Tumor	5.3	5.3
Neurological or Psychiatric Disease	2.1	0.2
All other Reasons ‡	6.8	6.8

* Neither the medical diagnosis nor the reason for advising contraception was noted on the records of one white and two Negro women.

† Mainly diabetes and thyroid disease.

‡ Includes arthritis, diseases of the gastrointestinal tract other than tumor, varicose veins, phlebitis, non-tuberculous diseases of the respiratory tract, obesity, dental caries, and infected tonsils.

anemia or general debility, and the remainder for other medical reasons.

In Spartanburg, almost all the women referred for contraceptive advice were also in need of some sort of gynecological care. More than 90 per cent had perineal and cervical lacerations, and about 80 per cent had cystocele or rectocele or both.¹⁵ Detailed data concerning medical findings are not available for any other group of women studied. Spartanburg data, however, show that among the type of women served by a county health department in a semi-rural southern area, there is ample reason for the establishment of contraceptive services from a purely medical point of view. It is obvious that if these women had become pregnant before their general health was improved, pregnancy would have constituted a hazard both to the mother and her child.

Even without established clinical services to advise couples on birth control methods, there are widespread attempts on the part of the population everywhere to space births and to limit the number of their offspring. Frequently, ineffective and harmful meth-

ods may be used through ignorance, and when these fail to prevent conception, there is resort to abortion, with resultant serious injury to health.

For the women to whom pregnancy would constitute a serious health hazard, there is no choice for the physician but to offer the most effective contraceptive methods available, to perform a sterilizing operation, or to counsel abstinence for long periods. No perfect contraceptive method has been discovered to date, but a number of methods can be highly effective, when acceptable to the couples using them and when used regularly and with care.

For groups given special advice on birth control, the pessary with jelly has proved very effective. This was the method prescribed for more than 90 per cent of the patients served in the New York, Cincinnati, and Spartanburg clinics, and when used it prevented between 80 and 95 per cent of the pregnancies which would have occurred had the couples used no contraception. In Spartanburg, the effectiveness ratio was about 80 per cent for both white and Negro patients; in Cincinnati, 90 per

cent; and in New York, 94 per cent. The use of other types of contraception was also highly effective after the women had learned something about the anatomy of coitus and the reasons for care and diligence in the use of all contraceptives. All types of contraception other than those prescribed were 92 per cent effective for New York couples, 72 per cent for Cincinnati couples, 81 per cent for Spartanburg white couples, and 55 per cent for Spartanburg Negroes.⁸

FIGURE 1—Per cent of increase in the effectiveness of the contraception used after clinic attendance over that used before clinic attendance, for four groups of women.

Figure 1 shows the per cent of increase in the effectiveness of all contraception used by the groups studied after they had been advised, over that used before they were advised. The greatest increase in effectiveness was in those groups in which preclinic contraceptive practice was relatively ineffective, the smallest among New York couples who had used contraception

very effectively before they attended a clinic.

The Logan group did not attend a maternal health clinic. The service there consisted in the distribution of contraceptive jelly by a nurse to all women in the area referred to her by doctors and to others who requested the service. Here, the emphasis was on general reduction of birth rates in a mining area of high fertility and extremely low economic status. The method prescribed was not so effective as those prescribed in areas where clinical facilities could be made available, but its use was followed by a reduction of 43 per cent in the pregnancy rates of the women in the area.⁹

Not all the women who came for or accepted advice on contraceptive methods, in the studies cited, used what was given them, but between 88 and 97 per cent made some attempt to use the methods prescribed.* The proportion of women who continued to use the prescribed methods decreased first rapidly and then more gradually, until a year after their first contact with a clinic, less than two-thirds of those women who were found and interviewed were still using the prescribed methods.⁸ Those giving up the use of the contraceptives prescribed for them turned to the methods in general use before they attended the clinics, and their use of these methods was, as has been noted, almost as effective in preventing pregnancy as were the presumably safer methods.

It was apparent in studying the material in detail that the training of patients to understand their own anatomy and the proper care of contraceptive devices is more important than the type of method prescribed, in achieving fertility control. Some couples prefer one type of method, some another, and still others may prefer to use several different

* For the per cent of women using types of contraception prescribed for them, in these and other studies, see Beebe, *op. cit.*, p. 155, Table 37.

methods in rotation. It is important that physicians and nurses prescribing contraception take individual choice of methods into account and instruct patients in the best use of the contraceptives of their choice. A method relatively ineffective for some couples may be highly effective for the couple liking it and using it diligently. Conversely, the most effective method is of no use to the couple who dislike it and will not use it.¹³

The single-mindedness with which occlusive vaginal methods are prescribed in most contraceptive clinics and by most physicians is obviously unsound. If between a third and half of the patients for whom pessary and jelly are prescribed give up their use within a year and more couples give them up as time goes on, it would seem wise to question patients closely concerning their choice of contraceptives and to advise them how best to use the contraceptives of their choice. Patients unacquainted with the use of pessary and jelly should be instructed to return for training in the use of other techniques if the one first prescribed is not satisfactory.

The U. S. Public Health Service, in 1941, declared its stand on the inclusion of contraceptive services in state maternal health programs in the following statement:

"It is the policy of the Public Health Service to cooperate with the health departments of the various states in the programs that they decide are in the best interest of the protection and advancement of the people they serve.

"Should a State Department of Health decide on its own initiative to undertake a child-spacing program in accordance with the health laws of the State, the Public Health Service would give the proposal the same consideration as would be given to any other proposal in connection with the health program of the state."*

A number of southern states have pioneered in including contraceptive

clinics and services in the maternal health programs in many of their county health units. These states are North Carolina, Alabama, South Carolina, Florida, Mississippi, and Texas. In these states the approval of the state medical society was sought and obtained before the program was instituted. The individual county medical societies also approved it before it was introduced into each county. The Planned Parenthood Federation has given technical aid and some subsidies for supplies as a means of encouraging the establishment of services under public health auspices. The types of service vary with available clinical facilities and range from the intramural clinic under county health department supervision, like that in Spartanburg, to the services of a visiting staff of public health nurses, who, in addition to their other duties, can instruct women in their homes in simple techniques requiring no fitting, when the need arises.

State medical societies of Georgia, West Virginia, and Virginia have recommended that these states establish contraceptive services for indigent women under state health department supervision. In addition, there are scattered clinics under local health department supervision in various places in the United States.¹⁶ More services will doubtless be established when trained physicians, now in the Army and Navy, become available.

Since 1941, the Council on Pharmacy and Chemistry of the American Medical Association has considered contraceptive drugs for acceptance on the same basis as other drugs, and standards for certain contraceptive products¹⁷ were accepted for inclusion in the 1944 edition of *New and Nonofficial Remedies*.

* Letter from the Acting Surgeon General, dated October 17, 1941, in response to a request for a statement of policy from the Planned Parenthood Federation of America. (The only states in which the prescription of contraception by a physician is illegal are Massachusetts and Connecticut.)

dies.¹⁷ This is an important step, designed to protect the public against the use of harmful and ineffective contraceptives.

Clinics for the diagnosis and treatment of sterility have been established in a number of cities in the United States, but none of them is under public health auspices. Most of them are in large hospitals because of the necessity of having laboratory and other facilities available, in order to determine, in each case, what may be the cause of sterility. The diagnosis and treatment of sterility are still in the experimental stage and, until more is known about them, it is unlikely that sterility clinics can be included in public health services. Health officers can and should encourage the study of the problem in those areas where facilities are available, because the existing data concerning the prevalence of involuntary childlessness suggest that between 5 and 10 per cent of all women may be sterile.¹⁸ When the Indianapolis study is completed we shall probably have more reliable data about sterility than are now available.

The control of fertility presents many problems which concern the public health. Maternal mortality and morbidity rates have been greatly reduced within the last few years by careful study and control of obstetrical practices. There remains a group of women, however, for whom pregnancy, even under the best medical supervision, constitutes a hazard to life and health. For the woman in this group it is imperative that pregnancy be prevented until her health is improved and it is no longer hazardous. She is entitled to sound medical advice concerning the means of preventing pregnancy.

The studies reviewed in this article have shown that contraception is widely practised, but that its effectiveness may be considerably increased by expert advice. It is probable that with more

attention to individual preferences in contraceptive methods, effectiveness and acceptability could be increased further.

Women of low economic status with high fertility and high morbidity and mortality rates are those for whom this type of care should be available under public health supervision. The U. S. Public Health Service has declared its willingness to aid such programs when they are initiated by the states. If and when such services are established, their policies should be determined by the results of past research. Plans for service should include continuing research and evaluation, to determine the quality and effectiveness of the service and its broad influence on maternal morbidity and mortality rates.

Comparison of Observed and Expected Deaths in Selective Service Registrants with Negative and Positive Serologic Tests for Syphilis

MURRAY C. BROWN, M.D.

Director of Medical Education, Meharry Medical College, Nashville, Tenn.

IT can be assumed that it is desirable for the epidemiologist to measure syphilis in those terms which have gained general usage in the description of other communicable diseases. While the nature and course of this disease have prevented collection of local data for incidence, morbidity, and mortality, attempts to remedy this situation have been reported in the literature. Development of techniques to provide acceptable information which may be used in place of these data has been a matter of concern.

Because syphilis is exceedingly chronic, incidence must be distinguished from prevalence. Techniques for measuring prevalence of syphilis are familiar. The serologic survey, either of an entire population, or of a large sample free from selection, is perhaps the most acceptable method. It is economical and requires no special facilities not generally available. While "serologic syphilis" is not necessarily clinical syphilis, to some extent the degree of error can be measured. It is of no greater significance than the error encountered in other techniques used to measure prevalence.

As a measurement which may be substituted for incidence, or "attack rate," for many demographic purposes, Turner has developed the "discovery rate."¹ The case he presents for this method of measuring syphilis for certain specific purposes is convincing.

It may therefore be said that information of practical value regarding the prevalence and incidence of syphilis may be collected.

Morbidity and mortality are another matter. Of the two, mortality is probably the more important. While morbidity produces economic and social results which are serious, these effects are observed in but a few individuals. Only those patients with late crippling lesions suffer noticeable disability, and they make up no more than 4 to 6 per cent of a syphilis population.

Death from syphilis, either due to late lesions or to acceleration of other disease processes, has seemed the significant factor. If this factor alone could be accurately determined, data concerning incidence and prevalence could be interpreted, and a community profile for syphilis could be developed. From such a profile the local economic, social, and medical significance of syphilis could be determined.

It is distressing to realize that, as Moore² observed, we know very little about syphilis as a cause of death de-

NOTE: This paper was prepared from materials collected by the Nashville Venereal Disease Control Program, City Health Department, Nashville, Tenn., during the author's incumbency as director.

spite four hundred years of study. Beyond the simple fact that some individuals die as the result of anatomic damage produced by this disease, little more can be said with certainty. The increased mortality to be expected from introduction of a given number of cases of syphilis into a community cannot be presently estimated with even fair accuracy.

The specific death rate for syphilis as reported in our vital statistics does not provide a measure of the mortality from syphilis in the community. Specific death rates calculated from death certificates cannot be used in a disease which is frequently undiagnosed or incorrectly diagnosed as a cause of death, nor can such rates be used when social and economical implications deter the physician from indicating the disease as a cause of death. The confidential death report³ has been devised to overcome the reluctance of the physician to indicate syphilis as a cause of death. This technique does not provide accurate death data for it does not compensate for the physicians' failure to recognize syphilis as a cause of death. There is also no means whereby the physician can properly evaluate and report syphilis as a contributing cause of death. The error introduced by these factors is probably excessive.

Schamberg⁴ has reviewed the approximately seventy papers on the prognosis of syphilis that make up the modern literature. While many of these were not directly concerned with methods of determining the number of deaths resulting from a given prevalence of syphilis in a community they all dealt with the outcome of infection with syphilis in terms of death. It would seem possible that such a wealth of material would provide sufficient information to make it possible to state with accuracy the number of deaths that should result from a given incidence or prevalence of syphilis. Certainly this is the material which furnishes the basis for statements about the serious nature of syphilis.

A few of the more pertinent papers are presented in Table 1. The difficulties in using the literature for demographic purposes can be inferred from examination of these samples, which are representative of the techniques employed. The careful study of autopsy material by Rosahn and Black-Schaffer⁵ is more accurate than demographic methods demand. Unfortunately it cannot be used to estimate the probable outcome of syphilis in a community. The population that comes to autopsy differs from a normal population. It is a hospital population

TABLE 1
Selected Studies of Syphilis and Death

* S. Miller, W. T.

in which economic and social selection operates and no correction for these differences can be made.

The study of Bruusgaard⁶ on the outcome of untreated syphilis might be usable if we could adjust for the effects of treatment on the prognosis of syphilis in the community. Sowder,⁷ however, has destroyed this possibility by his valid criticism of the selection that occurred in Bruusgaard's material.

Hall's analysis of The Actuarial Society's Medical Impairment Study of 1929 contains mortality data for syphilis by treatment status from the experience of all the American insurance companies.⁸ If the technical difficulties in using this material could be overcome, the information could not be applied to a community because the material studied was made up of policy holders. Possible economic selection, and the diagnostic techniques employed at the time the observations were made invalidate any conclusions from this study.

Usilton and Minor's study of the Coöperative Clinical Group material⁹ indicated that males suffered a shortened life expectancy when they had syphilis. This decreased expectancy was 17 per cent in Negroes and 30 per cent in whites. These findings are expressed as tentative death curves that could be used as a measure of the mortality to be expected from syphilis. Unfortunately the material studied was under observation in a clinic, a factor which involves selection. Table 2 demonstrates the difference which may exist

between a clinic syphilis population and a syphilis population obtained by examining an entire segment of a population. It will be noticed that the percentage of late syphilis with symptoms is approximately 50 per cent higher in the clinic population. Death attributable to syphilis is frequent among individuals with late syphilis. This suggests that mortality studies on clinic populations will exaggerate the rôle of syphilis as a cause of death.

The relationship of late symptomatic syphilis to death from syphilis is so direct that one might argue that the differences in the amount of late syphilis could be used as a correction factor. A correction factor of only 30 per cent applied to the Usilton and Miner figures would indicate that Negro males with syphilis outlive their uninfected fellows, while white males do quite as well in either category!

From these studies, and from the review of the defects of the usual demographic techniques, it is apparent that some as yet unreported method of determining mortality from syphilis must be developed if we are to have information for syphilis comparable to the specific death rate used in other communicable diseases.

Puffer,^{10a} Brailley,¹⁰ and other workers studying tuberculosis mortality have encountered similar problems and have developed means for examining mortality in that disease.

Puffer, et al. in 1942, reported a portion of a study of tuberculosis in

TABLE 2

1,161 Clinic Patients	8.4	27.3	58.0	6.3

Tennessee.^{10a} Incidental to one phase of this particular study it was desirable to evaluate the death rates from all causes for the household associates of the tuberculous index cases which were the subject of the investigation. This evaluation was accomplished by comparing the death rates for all causes, among household associates, with the rates prevailing for death from all causes among the similar age, sex, and color populations in the State of Tennessee. The technique employed involved obtaining the aggregate life experience of the household associates. "The average age-specific death rates of the colored population of Tennessee for the 5 year period 1934-1938 were then applied to the life experience of each age group. This procedure gave for each group the 'expected' number of deaths. These 'expected' deaths were compared with the deaths observed in the life experience of the household associates of tuberculous persons." Statistically significant excesses of observed deaths over "expected" deaths could be interpreted as the measures of the hazard introduced by the exposure of the observed population to tuberculosis.

It is reasonable to believe that the aggregate life experience of any population exposed to any unusual hazard of death could be studied by this method and the hazard could be measured by comparing the observed deaths from all causes with the "expected" deaths from all causes.

This method of studying mortality had interesting possibilities. To be applied to syphilis, certain information would have to be available. It would be necessary to have a syphilis population in which individuals could be identified. To accumulate the life experience for the study it would be necessary to know the date of diagnosis of each individual. The individual would have to be followed until he

died, was lost from observation, or until the close of the study period. The time between diagnosis and the close of the observation period would represent individual experience, and the aggregate of the individual experience would constitute the life experience. It would be of vital importance that the syphilis population studied be representative of syphilis in its distribution in the community by stage and degree of treatment, and that no other factor of selection carrying a hazard of death operate in this population which was not operative in the general community.

If these conditions could be fulfilled, any syphilis population which was representative of a statistically defined segment of a community could be studied, and differences found between "expected deaths" and observed deaths could be interpreted as the effect of syphilis in that particular age, sex, and color group.

The method was of particular interest because comparing expected and observed deaths from all causes involves no attempt to diagnose syphilis as the cause of death, yet should indicate the total effect of syphilis as both a contributory and a direct cause of death. In other words, the seriousness of syphilis as a hazard to life might be determined.

Selective Service provided a population which seemed susceptible to study by this method.

Table 3 presents the final distribution of the registrants of 10 Selective Service Boards which serve Nashville and the surrounding county. Registration was completed February 1, 1942. Between that date and February 1, 1944, when preinduction physical examinations were terminated in Tennessee, registrants were examined by local physicians. Each examination included a Standard Kahn test for syphilis, performed in the laboratories of the Tennessee State Department of Public Health. The name,

Ten Nashville Selective Service Boards*

<i>Registrants of 10 S.S. Boards</i>	<i>Total</i>	<i>Per cent</i>	<i>Number Serologically Examined</i>	<i>Per cent of Men Examined</i>	<i>Total Deaths Prior to 2-1-1944</i>
Total	66,037	100.0	33,987 (Est.)	51.4	603
White Only	50,692	76.8	24,000 (Est.)	47.0	328
Negro Only	15,345	23.2	9,987	65.1	275

age, color, address, parentage, and result of serologic test was on record for each man examined, at his Board. In addition the dated results of serologic tests were on record at the main offices of the Tennessee State Department of Public Health, by name, address, race, and age.

Table 3 also includes the number of deaths which occurred among men of Selective Service age who were presumed to be registrants of Nashville Boards, between the dates of respective registrations and February 1, 1944.

It will be seen that 15,345 Negroes made up about 23 per cent of the total registration while the deaths among Negroes were about 44 per cent of the total. Almost two-thirds of the Negro registrants had been examined with a serologic test. The prevalence of serologic syphilis was known from published reports for this area to be about 27 per cent among Negro registrants.¹¹ It, therefore, could be presumed that a fairly large sero-positive group of Negroes had been discovered by Selective Service examinations. The prevalence of positive tests among white Selective Service registrants was known to be about 4.5 per cent. Therefore, despite the greater number of white males examined it was likely that the positive white males would be only one-third as great in number as were the positive Negroes. The higher percentage of Negroes examined also minimized the possibility that selection for examination would introduce selec-

tive factors which would affect mortality.

The existence of a large and statistically identified sample of the population of Nashville and surrounding county which could be divided into persons with "serologic syphilis" and persons known to have negative serologic tests suggested the experimental application of the principles of the tuberculosis technique to a syphilis population.

It was realized that acceptance of "serologic syphilis" as a measure of prevalence of syphilis would introduce some error. Our own experience indicated that 3 per cent of the persons examined by Selective Service and found to have positive serologic tests for syphilis could be regarded as non-syphilitic after careful clinical study. It was also clear that some few persons with negative serologic tests did have syphilis but the majority of these would represent persons in stages of incubation or latency rather than persons in whom serious lesions were present. These errors compensated each other to some extent, and in any case did not seem great enough to contraindicate the study.

When the experimental method was developed it also became clear that it would be impossible to substitute careful diagnostic study of each case for the serologic test as a criterion for diagnosis. Despite the use of legal measures to support persuasion some persons could not be brought in for examina-

tions. This last factor decreased the size of the sample and introduced the same type of error demonstrated to exist in clinic populations by Table 2. While study of prognosis by the stage of disease would have been of clinical interest, it was not possible under the conditions.

It was also impossible to study the outcome by amount of treatment received. The same factors operated here. The sample would have been distorted by the conditions which would have made detailed histories possible. It is also true that the sample was too small for subdivision.

These are not serious objections. Specific death rates for other diseases reflect the quality of treatment that prevails in the community. The stage of disease is not of great importance except in clinical studies, and our interest was confined to the outcome of syphilis in whatever distribution by stage existed in our community. For our purposes, it seemed that the answer to be expected from study of the population described would be satisfactory.

In planning the study it became evident that no additional labor would be involved if mortality among the entire group of Negro registrants was studied; so plans were made to determine experience and observed deaths for the men with negative tests for syphilis and for the men who were not examined as well as those with positive tests.

Criteria were set for the determination of experience. Experience for the whole group was to begin with Selective Service registration and was to terminate on February 1, 1944.

Total registrants for each registration were drawn from the board records, and age distributions by usual 5 year periods were calculated from 1940 U. S. Census data. Men in each registration were credited with the months of experience between registration and February 1, 1944, and the totals calculated

as person-years of experience in the respective age groups.

The experience for the blood tested group was to start with the date of first serologic test by Selective Service and to terminate on February 1, 1944. Men sent to the army after this date were not given serologic tests by Selective Service. This information was collected by recording the date of serologic examination by the number of months it antedated February 1, 1944. The total person-months of experience were calculated from this material. Registrants were classified by the result of the first serologic test taken by the Selective Service System.

In order to confine the study to civilian experience, both deaths and experience occurring after induction were excluded. This was necessary because death hazards in the army are not comparable to those encountered in civilian life. Experience lost due to induction was calculated from date of induction of each registrant to February 1, 1944. This was charged to the proper group by result of serologic examination.

Deaths for the whole group were obtained by abstracting the resident and nonresident death certificates for Nashville and the surrounding county from October, 1940, to February, 1944, for the Selective Service age group. These were supplemented from the records of each Selective Service Board, clinic information and other sources. A death was chargeable to the Selective Service group only when positively identified by comparison of death certificate and the registrant's file in the Selective Service Board. The death was assigned to the proper group on the basis of the first serologic test reported on the Selective Service physical examination record.

All determinations were done on an age-specific basis by years. Ages on death reports were adjusted to age at time of serologic test. Source material

40-44	592	216	36.5	364	61.5	12	2.0
Total	9,834	2,719	27.6	6,912	70.3	203	2.1

included quadruplicate laboratory forms in the Tennessee Department of Public Health, Selective Service Board induction records, and the files for individual registrants in each board.

The first information tabulated for the entire study was the result of serologic tests of Negro registrants by age and result of test. This information is contained in Table 4. The total per cent positive agrees closely with the previous reports for Negro males in Nashville.¹¹ The slight excess, 27.6 per cent compared to 26.8 per cent reported previously can be accounted for by the inclusion of more men between 35 and 44 years in this sample. The size of the negative and positive populations available for study is shown by age group. Aside from the small numbers for the extremes of age, the number of men is relatively even and of a size permitting analysis, provided experience per man is adequate. The rates for sero-positivity increase on a smooth curve for age—a result which was expected.

The information on deaths became available while experience was still being determined. It was disturbing to discover that, of 275 deaths occurring among Negro registrants, only 92 occurred among men who had been serologically examined. It was recognized that experience per man in the unexamined group far exceeded the experi-

ence per man in the examined portion, but the latter group was twice as large. The collection of twice as many deaths in the smaller group at once raised the possibility that the selection of men for blood testing introduced a serious sampling error. Examination of the death certificates showed no marked dissimilarity between the distribution of causes of death in either group. All death certificates were then checked against the respective registrant's Selective Service file to see if any had been excluded from examination on the basis of known physical defects. No selection on physical grounds was demonstrated.

Table 5, which presents the result of calculating death rates for all causes for the Selective Service registrants with negative serologic tests and for the entire group of Negro registrants, supports the belief that no such selection occurred.

The rates derived are irregular, but by removal of the extreme age groups in which the number of men was very small and for which experience is obviously inadequate, much of this uneven gradient disappears. These death rates are compared with statewide rates for Tennessee Negroes. The difference in total rates for each of these three populations is seen to be small. The lowest rate is that for the entire Negro Selective Service population

TABLE 5

Death Rates for Negro Males by Age

All Negro Registrants Compared with Registrants with Negative S.T.S. and with Tennessee State Rates; Including Actual Deaths and Experience for Nashville S.S. Area

Age	Registrants with Negative S.T.S.			All Registrants			Tenn. 1942 Rate
	Deaths	Experience	Rate	Deaths	Experience	Rate	
Under 20	4	188	21.3	12	2,009	6.0	4.4
20-24	7	1,726	4.1	44	8,799	5.0	7.7
25-29	15	1,412	10.6	60	8,050	7.5	7.7
30-34	13	1,172	11.1	73	7,220	10.1	8.5
35-39	6	724	8.3	47	5,961	7.9	12.1
40-44	4	408	9.8	35	3,405	10.3	12.1
Total	49	5,630	8.7	271	35,444	7.6	8.4

which indicates that selection of low risk persons for blood testing probably did not occur. The mean age for each total group is similar.

The sex, age, color-specific Tennessee state rate¹² is similar to the experimental rates in Table 5 but shows an even gradient from younger to older ages. The stability of this rate is of course due to the large experience on which it is calculated, and the instability of the experimental rates reflects the small experience from which they are derived.

Table 6 presents the results of applying the Tennessee State age-specific death rate for Negroes to the experience in both the negative and positive Selective Service populations to determine the number of deaths expected for each group. Both experimental populations exclude the 350 years' experience for 208 men with doubtful blood tests.

This experience resulted in no deaths, and its exclusion does not affect the results materially.

These expected deaths are compared with the actual number of deaths experienced in each experimental group. The negative group shows exactly normal mortality while there is a slight excess mortality for sero-positive registrants. This excess lies well within limits of pure chance occurrence. Age 45 was excluded from Table 6 for convenience in both groups, and contains one sero-positive death. Adding this death to the total deaths of sero-positive registrants will not make an observed difference in mortality which is significant.

Among the deaths syphilis is not once reported as the cause of death, or the contributory cause of death, for a serologically examined man. One death certificate for a sero-positive man states

TABLE 6

*Deaths S.T.S. Positive and Negative Negro Registrants
With Expected Deaths by Tennessee State Rates
Including Experience for Nashville Selective Service Area*

Age	S.T.S. Positive		Expected Deaths Tenn. Experience (1942)	S.T.S. Negative		Expected Deaths Tenn. Experience, 1942
	Experience Man-Years	Deaths Actual		Experience Man-Years	Deaths Actual	
Under 20	113	1	2.4	188	4	0.8
20-24	976	8	4.0	1,726	7	13.3
25-29	1,099	9	11.6	1,412	15	10.9
30-34	1,056	12	11.7	1,172	13	10.0
35-44	951	12	8.0	1,132	10	13.7
Total	4,215	42	27.7	5,530	49	48.7

aortic regurgitation and uremia as the cause of death. This of course cannot be distinguished from aortic regurgitation from rheumatic fever but was presumably of syphilitic origin.

Reports for registrants with negative serologic tests include one death of a known syphilitic in the 25-29 year age group. Search of hospital, clinic, and morbidity reports for recent years revealed no other deaths involving clinical syphilis in this group.

Two deaths in the sero-negative group may have been due to syphilis but probably were not. Organic heart disease was reported on one death certificate, and cerebral hemorrhage on the other.

Autopsy was performed in several instances among the unexamined registrants, but no autopsies are reported for either sero-positive or sero-negative cases.

Search for previous clinical records for dead men in the group with no serologic examination revealed a total of 35 deaths with previous clinical diagnoses of syphilis. Thus 19 per cent of the dead not examined by Selective Service were known to have syphilis. While the point can be determined, no check has been made to determine the number of sero-positive living men who were known to treatment agencies prior to examination by the Selective Service Board.

The positive and negative men show no gross difference in physical status. The percentage of sero-negative men deferred on physical grounds is similar to the percentage of men classified "4-F" for causes other than syphilis in the sero-positive group.

DISCUSSION

It will be possible to continue observation of this population for several years. The serological examinations by local boards are now concluded, so information about this population from

that source is complete. Future experience can be accumulated without repeating the more laborious portion of the study. Two things limit the time for which the present data will have value. The occurrence of new syphilis in this group may be expected to assume such serious proportions in a few years that the sero-negative population will no longer be a control, nor the sero-positive population representative of syphilis in the portion of the community studied. The other limitation will be the change in residence which will inevitably occur and which will conceal deaths among this population. This is not serious until sufficient time elapses to make these registrants residents of their new community. Two or three years will be required to produce these changes, and possibly they will not occur for five years.

While the difference in mortality found in favor of serologic syphilis is not significant, when this is converted into a death rate a figure of 106 deaths per 100,000 is obtained. If the true specific death rate for syphilis among Negroes 18 to 45 is of this order, syphilis carries a serious hazard for young Negro males. The death rate for cancer among Negroes of all ages in Nashville is only 151 per 100,000. To reach a significant difference in mortality in the experience studied, a death rate exceeding 200 per 100,000 for age 18 to 45 is required.

The method presented is most adaptable to large populations with high prevalence rates for syphilis. States in which serologic testing was part of the Selective Service registration procedure already have accumulated two and one-half times as much experience for the positive portion of their 21-35 year registrants as was accumulated in Nashville through January, 1944. It is possible that significant differences could be determined in these states now, while in states with universal blood

testing laws the opportunity exists, by correct design of the serologic form, to identify the entire population in a manner which will permit the relation of deaths to the serologic status of the dead person.

SUMMARY

The study of deaths in syphilis presents a real challenge. Present information is extremely limited, both by the nature of the disease and social implications which deter physicians from indicating this cause of death on death certificates. Specific death rates, applicable in other communicable diseases are deficient when applied to syphilis. Other methods of studying death have not been satisfactory for demographic purposes.

The deaths occurring among 15,345 Negro registrants in Nashville's ten Selective Service Boards have been studied. Deaths experienced among the sero-negative and sero-positive portions of this group have been compared with the expected deaths as calculated from Tennessee age, sex, and color-specific death rates for all causes.

The material is presented in order that the method used for collecting the information may be examined. The study was limited to civilian experience and civilian deaths to exclude the uncertain death reporting and unusual hazards encountered in the army. The Negro portion of the registrants in Nashville was analyzed because the group is small and syphilis is extremely prevalent in that group.

The results of the experimental study of Negro registrants are not conclusive. Some excess mortality was found in the sero-positive group. This excess does not approach the proportions of the possible error due to chance. The short experience of the small group of men studied made it unlikely that other results would be found. The method

applied is such that future experience can be accumulated with little effort, and it is possible that restudy will provide conclusive evidence of the effect syphilis has upon mortality.

Material presented includes the final results for serologic examinations performed on Negro registrants of Nashville by Selective Service. Tables of death rates for sero-negative, sero-positive, and all Negro registrants of Nashville's ten Selective Service Boards are presented which indicate that factors of selection of Negro males for blood testing did not seriously distort the mortality information.

Development of a Community Rheumatic Fever Program

BERNICE G. WEDUM, M.D.

Denver Area Rheumatic Fever Diagnostic Service and Department of Medicine, University of Colorado School of Medicine, Denver, Colo.

THERE are indications that coördinated programs designed to meet all needs of the patient with rheumatic fever are favorably influencing morbidity and mortality^{1, 2} although clear-cut proof is lacking.³ Unfortunately most plans begin before the local prevalence of the disease is accurately determined. Lack of this knowledge will make future evaluation difficult. Although it is not yet known with certainty whether rheumatic fever programs are preventing illness or prolonging lives, substitution of good management for the neglect or over-protection which frequently characterizes the handling of these children is enough to make such programs worth while.

There have been recommendations by various groups that all components of a program be available before one is initiated.⁴ This is greatly to be desired but in many areas it is not possible. The great lack is usually beds for long-term convalescence. There seems to be little doubt that institutional convalescent care or hospital schools give the best results with most bedridden rheumatic children.^{5, 6} Yet this lack need not necessarily deter the inauguration of a program. Home care will be all that will be available in many areas for some time to come. The nature of rheumatic fever is such that individuals of all income levels must be reached. Even after the provision of convalescent beds many children will

still receive care in their homes. There are other benefits derived from a rheumatic fever program even without an adequate foster or convalescent home. These include case finding, observation of siblings, home teaching, vocational guidance, follow-up in the schools, lay and professional education, and restoration to normal life of the child incorrectly labeled rheumatic.

In the discussion which follows an attempt will be made to show how a community may be organized when all the components of a complete rheumatic fever program are not present. The activities described below focus attention on the missing elements and stimulate the community to provide them.

ORDERLY EVOLUTION OF A RHEUMATIC FEVER PROGRAM

In order to interest a few key people in the beginning, certain publications are of value.^{2, 7-12} A brief summary of the operation and results of the London County Council Rheumatism Scheme⁷ with preliminary analysis of the facilities and needs in the community is also helpful.

PREVALENCE STUDIES

There are several publications which summarize for rheumatic fever its importance as a cause of death in children,^{2, 7} its prevalence in school children,^{13, 14} and the prognosis.¹⁵⁻¹⁷ These general statistics are helpful, but the figures which carry the most

weight are those which apply to the specific community involved. There are two presentations which are very effective. One is a table showing the principal causes of death in children aged 5 to 19 in the city and state concerned. This can easily be obtained by calculation from the U. S. Bureau of the Census records.¹⁸ Rheumatic heart disease is the first cause of death among school children in many areas. A second presentation may show the comparative standing of the city and state. For example, in 1939-1940 Denver had the second highest mortality rate in children among the 25 largest cities in the United States. In this connection Hedley's figures for 1922-1936¹⁹ can be used as well as current census reports.

Prior to the initiation of the program it might be well to determine the amount of hospitalized and convalescent rheumatic heart disease, rheumatic fever and chorea in the community. Such a survey will arouse interest and provide another base line for future comparison.

Another preliminary procedure of value is the determination of the prevalence of rheumatic heart disease in a representative sample of school children.^{7, 13} Such a study can be of great value in estimating the effect of a rheumatic program if repeated after 5 or 10 years. Ideally a nearby group of children which is not to receive the benefits of the program is also surveyed to serve as a control group. The principal difficulty lies in securing the services of a physician trained in the study of heart disease in children. One solution is to have this survey done by the physician who will do all or the major portion of the clinical work in the proposed rheumatic fever program. The health department of the public schools might employ such a physician part time for about 6 months prior to opening of the diagnostic services. Such

studies furnish good material for local statistics of prevalence, establish a good working relationship with the doctors and nurses in the public schools, and provide a group of cases with which to start the diagnostic service.

A complete report may then be written which outlines the local problem, the ideal program, the facilities available in the community and how they can be adapted to the need.

DIAGNOSTIC AND CONSULTATIVE SERVICES

Diagnostic and consultation services are the first requirement so that the children who are to receive the benefits of the program are accurately identified. The diagnosis in many cases requires laboratory, x-ray, and electrocardiographic procedures which are beyond the means of the average individual, and beyond the equipment of many physicians. Another matter to consider is that many children are erroneously diagnosed as having rheumatic fever or heart disease because of the presence of a few leg pains at night or a functional systolic murmur. It is as important to remove the rheumatic label from these children as it is to identify the child who has the disease.²⁰

The health service of the public schools can play a major rôle in launching a diagnostic service. In the course of school health examinations a number of children are found who are thought to have heart disease. Indigent patients in this group can be the first studied. Children who have a physician are seen after the latter's permission has been obtained by the school health service. Later patients will be referred directly by physicians, public health and visiting nurses, clinics and other agencies. In every case a report of the findings should be sent to the source of referral and a copy to the school health service. A child with rheumatic fever or other condition is

directed to medical supervision, if he is not under care, or referred back to his own physician.

A RHEUMATIC REGISTER

An accurate rheumatic register automatically evolves from the activities of a diagnostic service. This register has the names of children who are to receive a coördinated program of care and follow-up as described below. The superiority of a rheumatic register to a list obtained by reporting has been discussed elsewhere.²⁰ When a diagnostic service is available to which any child with manifestations suggesting rheumatic fever can be sent for study, the physician receives a report which is a valuable aid in the management of his patient. At the present time, in most localities, reporting the disease is usually an additional piece of paper work for which the physician receives nothing in return, while health authorities receive the name of a child who may or may not have rheumatic fever.

EDUCATION

Parallel with the development of diagnostic services, a program of professional education may be instituted. Physicians should be reached first. Such education can take the form of a refresher course with outside speakers invited, an abstract service for physicians, a series of articles on the manifestations, differential diagnosis and treatment of rheumatic fever appearing in a local medical journal, and "rheumatic fever nights" at meetings of the medical society. The activities of the diagnostic service are in themselves a potent form of education.

Many errors in diagnosis and treatment are being made. One notable one is the frequent use of the sulfonamide derivatives in the treatment of acute rheumatic fever, which has been shown by several investigators to be not only ineffective but harmful.^{21, 22} The

articles published on this point simply have not reached many overworked doctors. It has been our experience that the great majority of busy physicians welcome such information if it is given in dignified and understanding fashion. It must be borne in mind that there is no disease in which the so-called physician-patient relationship is more greatly needed than in rheumatic fever. These children and young people must have a family doctor to whom they can refer for supervision and guidance, and this individual must have at his disposal expert consultation, up-to-date information, and coördinated facilities for care.

The same program of education should be instituted among nurses. This professional group is usually aware of the rheumatic fever problem, but many are not familiar with slight signs of activity, and fine points of nursing care both in the hospital and in the home. In a similar manner all groups concerned with the care of the rheumatic child, including social workers, home teachers, dietitians, and occupational therapists should be reached.

Only after the professional groups are educated should much attempt be made to reach the lay public. It is usually an error to arouse the public to a need before professional groups are ready to cope with it. Materials which can be obtained from the Metropolitan Life Insurance Company, the Children's Bureau, and the American Heart Association are invaluable.

COÖRDINATION

Coördination of the agencies already existing which can supply care follows education of professional groups. A "nerve center" is needed through which all activities concerning the care of rheumatic children are integrated. No effort can be made to coördinate the services offered by the groups mentioned above until one is certain that these

groups are familiar with the special problems of rheumatic fever. For example, injudicious management of the child with slight cardiac damage can create a mental invalid. Education of these professional groups should precede coördination.

It is suggested that if no effort of this nature has been made previously or if confusion and overlapping of agencies exist, a small "pilot plan" of coördination be tried unofficially, enlisting the aid of a few interested family physicians and clinics and involving not more than 20 or 30 children. In this manner the kinks can be ironed out on a small scale before such service is offered widely.

This center must be one with which the private physician can quickly make any arrangements for home care, one through which reports can be efficiently transmitted, and where the rheumatic register will be maintained. Eventually these activities will probably be a part of municipal or state health departments. They will, however, range all the way from a small part of the duties of one public health nurse, working in a county where rheumatic fever is not very common, a part of the function of a diagnostic service in a moderate sized community, to a separate complex organization in a city of a-half million or more. This center acts as a clearing house for all those associated with the management of the rheumatic child.

FOLLOW-UP

This function falls logically to the school health service. In each school should be a file of rheumatic children and their siblings. Such children are reminded to visit their physicians every six months, are observed at intervals for slight manifestations of rheumatic activity and receive health educational material. Education is carried on through parent-teacher associations. Only some of the many possibilities are

mentioned.⁹ If this has not been tried previously it might be attempted in one school and, when running smoothly, put into effect throughout the entire school system.

Children with a clear-cut history of rheumatic fever or with obvious rheumatic heart disease, on whom the family doctor and the school physician agree are not always seen in the diagnostic service unless there is a problem. They should be reported to the coördinating center and added to the rheumatic register.

With the background of a community awakening to the rheumatic fever problem, efforts can be made to obtain those parts of a program which are lacking. For example, in Denver a large sum of money was given for a convalescent home partly as a result of the stimulus of a rheumatic fever program.

PROBLEMS ENCOUNTERED

In setting up a rheumatic fever program it is necessary to have (1) one or two, or a few individuals with special knowledge of the disease who are willing and eager to devote a great deal of time to the project, and (2) a local sponsoring agency. In each community this agency will differ, depending on its strength, composition, and influence. A program sponsored by an outside agency lacks the local pride and enthusiasm so important for success. If an outside mode of organization is necessary, the sponsorship of a local community group should be enlisted as soon as possible.

A difficulty may arise if the sponsoring group undertakes the formulation of the program. The program can be formulated only by those thoroughly familiar with the disease. An example may be cited: A sponsoring group contemplated the creation of a diagnostic service where one of the rules was that each child be seen only once.

This reasoning by analogy with local tuberculosis diagnostic clinics would not apply to rheumatic fever, as those familiar with the disease know. However, once the sponsoring agency understands what is needed, its knowledge of local persons and situations frequently makes it better able to solve the problems involved in launching a program.

In drawing up the detailed plan of organization, rules of procedure, eligibility, and budget, much can be learned by studying published reports^{10, 20, 23-28} and by writing for sample forms and charts.

In selection of the personnel for a diagnostic service, certain points are of great importance. Inevitably a great amount of attention centers around the heart. The individuals responsible for the evaluation of these children must have good ears, regardless of their specialty. The recognition of the rheumatic state is ultimately clinical, and at least one physician should have considerable experience with rheumatic children at all stages of the disease. A diagnostic service should never become simply a screening or classification center where the examination is carried only to the point of determining whether or not the child has rheumatic fever or heart disease. Aside from detracting from the quality of the examinations performed, there is a very practical reason in that it is frequently impossible to state that a child does not have rheumatic fever unless one can explain his symptoms on some other basis. A combination of an internist, a pediatrician, and one physician specially interested in rheumatic fever provides a team whose members supplement one another well.

Every effort should be made to obtain the services of the best trained people the community can offer. It frequently happens that individuals who are "naturals" as far as cardiology is

concerned are not suited by inclination or temperament to be contact men in a political sense for a large rheumatic fever program; and the reverse is even more commonly true. Rarely these qualities are combined in one person. If not, two or more individuals must work together in the capacities best suited to them. A diagnostic service needs somewhere in its organization a physician who has the confidence of the great majority of doctors in the community, regardless of his special knowledge of rheumatic fever.

A few other points may be mentioned briefly. It is suggested that the diagnostic service conform to the standards for a Cardiac Clinic as outlined by the American Heart Association. The physician actually running the service should have adequate authority and responsibility, including the selection of other clinic personnel. It is wise to give a physician working full time in a rheumatic fever program consultation privileges to avoid losing such individuals just as they become of great value. Such a service may be a center of research and clinical training for interested doctors, especially school physicians. Residents, internes, medical students, and student nurses should be included if the service is located in a medical school.

The official approval of the local county medical society is very desirable. Because of the feeling concerning "socialized medicine," any program dealing with private patients is likely to be viewed with distrust initially, but with proper operation of the service this will be replaced by confidence and appreciation. The principle of free choice of medical care should guide the operation of the service.

When coördination of facilities for care is considered, a problem may arise in the form of weak or faulty local health organization so that the agency which might logically take on this function is

not suitable. It may be necessary for some other department to serve. The actual persons involved are really of the greatest importance. It is best initially to have such activities carried on by those who have deep interest in the rheumatic fever program, with a record of accomplishment and the confidence of the community regardless of their official connection.

When a rheumatic fever program is started for children it may be difficult to expand it to include young adults. The high incidence of rheumatic fever among members of the armed forces²⁹ indicates that, in the future, programs should not be inaugurated without including these young adults. It is disturbing to see persons in their twenties walk into a clinic with the arthritis of long undiagnosed rheumatic fever and associated well developed heart disease.

FUNDS

Sources of funds for these programs include federal,³⁰ state, and municipal governments, the community chests, and a large number of benevolent organizations. The financing of a local program can be done either entirely by one organization or by several working jointly. Rheumatic fever deserves as prominent a place in the public eye as tuberculosis, poliomyelitis, and cancer. An American Council on Rheumatic Fever has recently been formed.³¹ Possibly at some future date rheumatic fever will be included in a nation-wide campaign to raise money to combat all forms of heart disease. Ultimately such an organization would conform to whatever solution is finally made of the problem of large numbers of volunteer agencies competing with one another for community support.³² The situation will vary so with different cities that only general statements can be made. However, it is suggested that rheumatic fever be included in the health activities of every community

chest. Among other groups who have aided are tuberculosis associations, the American Legion, Lion's Clubs, and Parent-Teacher Associations.

SUMMARY

1. Although it is desirable to have all components of a complete rheumatic fever program before one is inaugurated, in many areas this is not possible. It is suggested that plans be initiated, utilizing and perfecting what facilities are available. The operation of a program is an effective means of focusing attention on the components which are not present, and stimulates a community to provide them.

2. A rheumatic fever program may evolve in the following manner:

1. Prevalence studies
2. Diagnostic services and rheumatic register
3. Education of professional groups
4. Coördination of services already available
5. Education of the lay public
6. Organized efforts to obtain facilities not available

Certain parts of this program and problems that may be encountered are discussed in detail.

3. Young adults as well as children need the benefits of a rheumatic fever program.

4. All income levels should be served. Most rheumatic fever is seen by the family physician who requires at his disposal expert consultative and diagnostic services and coördinated facilities for care.

You Can't Pigeon-Hole Health

"Low income, bad housing and environment, ignorance, high incidence of sickness and mortality, low income—all these continue endlessly in a vicious circle. Health agencies must learn, as welfare agencies have been learning, that these recognizable defects of the common life cannot be remedied by themselves. It is not contended that a health agency can affect the wages of unskilled workers, nor remove them from slums, nor give them basic education. But it is significant that organizations whose purpose is to promote health and to prevent disease should give so little attention to these basic

conditions. This is understandable only on the assumption that close devotion to the immediate demands of their specialized task shuts from them all awareness as to the other essentials of wholesome living. A vigorous and vital national health council, having as its objective the building of health to the highest point possible, would have to take cognizance of these basic factors and could at least add its voice to those calling for opportunity for fuller life for all the people."—Gunn, Selskar M., and Platt, Philip S. *Voluntary Health Agencies*. New York: Ronald Press, 1945. 364 pp. \$3.00.

Experiences with Rheumatic Fever in the Army Air Forces

CHARLES A. R. CONNOR, M.D.*

Instructor in Medicine, New York University College of Medicine, New York, N. Y.

THIS paper reviews some of the experience of the Army Air Force Rheumatic Fever Control Program. It treats briefly the relationship of rheumatic fever to group A streptococcal infections; chemoprophylaxis; therapy in the acute phase; and a new concept in the management of the convalescent phase.

No accurate statistics on the incidence of rheumatic fever in this country are available. An obvious reason for this state of affairs is the lack of specific knowledge of the etiology and also the lack of a specific diagnostic test. Since the clinical syndrome rheumatic fever presents a variety of signs and symptoms, none of which are pathognomonic, a positive diagnosis depends upon the critical evaluation of these data.

In our studies we were confronted with two major difficulties in the consideration of this diagnosis in atypical forms of the disease. The first was the reluctance to make such a diagnosis, because of the possible effect on the patient's future emotional and psychological well-being, as well as on his future insurability and employability.¹ This conservative attitude may be commendable, in view of the undue emphasis in some educational programs on the serious sequelae of rheumatic fever, but it prevents standardization in gathering

figures on incidence. The second, in our opinion totally unjustifiable, was to accept the diagnosis on the basis of the therapeutic response to salicylates. Jones has called attention to this fallacy.² We have seen proven cases of rheumatic fever which had little or no subjective or objective response to large doses of salicylates. Conversely we have seen patients with bizarre arthralgias and myalgias whose symptoms were relieved with this type of therapy. Salicylates in large doses also can decrease the erythrocyte sedimentation rate, without altering the course of the disease.³ During the course of salicylate therapy, with serum levels of 300 gamma per ml. or higher, Murphy has observed the development of characteristic rheumatic lesions in tendons, the heart, the lungs, and in other sites.⁴

RELATION TO GROUP A STREPTOCOCCAL DISEASE

Table 1 shows the number of cases of acute rheumatic fever at six stations at which the criteria for diagnosis were standardized.² At all these posts the type of personnel and the military training program remained essentially unchanged over the period of 1943 and 1944. This table indicates that the disease was more frequent in certain sections of this country and that variations occurred from one year to the next. These variations could not be solely related to sulfonamide prophylaxis.

* Cardiologist, New York City Department of Health. Formerly associated with A.A.F. Rheumatic Fever Control Program.

TABLE 1

Location of Station Hospital	Cases of Acute Rheumatic Fever Admitted to Hospital		Military Activity	Approximate Average Strength	Chemoprophylaxis	
	1943	1944			1943	1944
Colorado	387	373	Basic Training, Technical Schools	12,000	None	¹
North Texas	58	87	Basic Training, Mechanics Schools	16,000	None	²
Wisconsin	94	106	Technical School	15,000	None	³
South Dakota	212	83	Technical School	14,000	None	⁴

Iowa	13	19	Advanced Flying Training	4,000	None	None

¹ Sulfadiazine prophylaxis used in winter of 1944. Experimental program. Results were inconclusive.
² Sulfadiazine prophylaxis used one day in winter of 1944 because of threat of meningococcus infections.
³ Sulfadiazine prophylaxis used continuously for 21 days in April, 1944. See figures relating to "Post B," Holbrook, W. P., *J.A.M.A.*, 126:84-87 (Sept. 9), 1944.
⁴ Sulfadiazine prophylaxis used in February and March, 1944. Hodges, R. G., *New England J. Med.*, 231:817-820 (Dec. 21), 1944. The author attributes the lessened incidence of rheumatic fever to the sulfa-prophylaxis.

laxis. A complete explanation of them is unknown to us. Grouping and typing of hemolytic streptococci were first performed in special laboratories at Air Force hospitals in the early part of 1944, so correlation of rheumatic fever and streptococcal disease are not available prior to this time.

The total number of rheumatic fever patients hospitalized in 1945 is not available, as the final reports following disposition have not been received. It is known, however, that the incidence was greatly reduced. The incidence rates for streptococcal diseases were also lower than those of previous years. A large amount of streptococcal disease during 1945 was caused by a sulfadiazine resistant group A type 17 organism, following which an appreciable amount of rheumatic fever might have been expected. The United States Navy had epidemics of respiratory disease caused by a sulfa-resistant type 17 streptococcus, with approximately 2 per cent of these cases subsequently developing rheumatic fever, according to Commander Coburn.

The first epidemic in the Air Forces of streptococcal disease caused by this type 17 strain broke out in a field on the Gulf coast of Mississippi late in December, 1944.⁵ This field had an

established special laboratory equipped to perform grouping and typing of streptococci by the capillary precipitin techniques of Lancefield.⁶ Type 17 streptococcus had not been isolated from patients with respiratory infections admitted to the hospital nor from routine bacteriological surveys of samples of the post population in the three months immediately preceding the onset of the epidemic. It is estimated that at least 1,000 men became ill with respiratory diseases caused by this strain of streptococcus, even though the entire population of the field was placed on one gram of sulfadiazine daily as a prophylactic measure. The diagnosis was proved clinically and bacteriologically in 271 soldiers admitted to the hospital. Only one case of acute rheumatic fever developed.

Similar type 17 epidemics occurred in February and March, 1945, at the fields in Colorado* and North Texas.⁷ The personnel of both of these fields were also placed on a regimen of sulfonamide prophylaxis, following which other types of hemolytic streptococci previously common were seldom found in throat cultures of individuals hos-

* In 1945, there was no basic training at this field, so that the strength was reduced by half and composed for the most part of seasoned men.

pitalized with respiratory infections. Six cases of rheumatic fever were admitted to the hospital in Colorado and 10 cases to the hospital in North Texas during the course of the epidemics. At neither field did rheumatic fever develop in an individual hospitalized for a respiratory infection caused by type 17 streptococcus. Four of the cases at the North Texas post had type 17 present in their throat cultures on admission for rheumatic fever.⁸ This finding was considered to represent a carrier state, although previous infection could not be excluded.

At the other four fields listed in Table 1 there was no outbreak of streptococcus respiratory diseases caused by this type 17 organism. The field in Wisconsin had a sulfadiazine sensitive group A type 19 streptococcus epidemic. One-half of the school population at this post was placed on a sulfa-prophylaxis program; 22 cases of rheumatic fever occurred during that period (Table 2).¹⁰ This experience will be discussed under the section on chemoprophylaxis.

Jennings and his coworkers¹¹ investigated the relationship of rheumatic fever to respiratory diseases for a full year at a large camp in Utah; their results are shown graphically in Chart 1. As a basis for this information, throat cultures were obtained on all enlisted personnel admitted from the camp to the hospital for acute respiratory diseases, including scarlet fever and pneumonia. These cultures were examined for hemolytic streptococci, which, when found, were grouped and typed by the Lancefield precipitin techniques.

The curve for rheumatic fever cases is plotted on a scale ten times larger than that for the other two curves. It includes only cases from the enlisted complement of the camp who had been stationed there for a minimum of two weeks.

As the authors point out, there are

many reasons why these three curves should be taken as indices rather than actual measurements. Only hospitalized cases of respiratory diseases are included, whereas it has been noted by many observers that attacks of rheumatic fever may be preceded by respiratory infections too mild to require hospitalization. The incubation period of rheumatic fever is considerably longer than that of acute respiratory disease, and the rapid turnover of personnel may have resulted in the loss of patients in this stage of rheumatic fever.

In spite of these qualifications, it is seen that the trend of the incidence of acute rheumatic fever follows closely that of group A streptococcal respiratory disease. This correlation occurred not only during a period of high incidence of group A streptococcal respiratory diseases (March to June) and a period of low incidence (July to September), but also during a period in which nonstreptococcal respiratory infections were frequent, although group A streptococcal diseases were almost absent (October to February).

Attempts to demonstrate a relationship between the incidence of acute rheumatic fever and individual types of group A streptococci were unsuccessful at this camp as has been reported by others.⁹

In the Rocky Mountain area where the incidence of rheumatic fever was highest for all the United States armed services and also in the Canadian Army,¹² one Air Force post, used as a training school for clerks, had relatively few cases of rheumatic fever and also a low rate for hemolytic streptococcal disease. (A special streptococcus laboratory was not established at this post; the hospital was equipped to do ordinary bacteriological examinations.) This post was located within a 25 mile radius of two other stations which had the greatest number of rheumatic fever patients and high streptococcal disease

CHART 1—The Relative Frequency of Respiratory Diseases and Rheumatic Fever, Kearns, Utah,
February 19, 1944, to February 23, 1945
Three point moving averages of weekly cases

Respiratory diseases dated by admission, rheumatic fever by onset

rates each winter and spring. This post in the foothills of the Rocky Mountains was used as a control in a study of 120 rheumatic fever patients

to determine the effect of altitude and climate on convalescence. Sixty patients were placed on this post while a comparable group of 60 cases was

evacuated by air to southern Arizona. All patients at the control station recovered clinically as well and as rapidly as at the southwestern field, and during a period of six months, there were no recrudescences of rheumatic fever.¹³ Actually both groups were convalescing in areas of low incidence of group A streptococcal disease.

CHEMOPROPHYLAXIS

Sulfadiazine prophylaxis was widely used in the Army and Navy during the war. In the discussion of the Navy program for the control of streptococcal infections Coburn states that the incidence of rheumatic fever among men receiving chemoprophylaxis was 15 per cent of the incidence in control groups.¹⁴ In the Army Air Forces sulfadiazine was not used in the same manner or extent as in the Navy. Fortunately, we were not confronted with the serious epidemics that occurred in several Navy "boot camps."

A thorough study at a large technical school in Wisconsin conducted by Warren demonstrated no effect in the reduction of rheumatic fever.¹⁰ Table 2 shows the total man-days of exposure of a control and treated (one gram of sulfadiazine daily) group and the actual number of cases of acute rheumatic fever hospitalized in each group. Calculating the number of cases expected in the treated group, using the control group as a base, showed that one case less than expected occurred.

Investigation of the effectiveness of salicylates and of sulfonamides in preventing the occurrence of acute rheu-

matic fever after the onset of an acute group A streptococcal respiratory infection was undertaken. In a single winter month at a Colorado post 275 acute respiratory infections, in whose throat cultures hemolytic streptococci were found, were divided into three groups.¹⁵ Symptomatic therapy was given to 130 during their hospitalization; 15, or 11.5 per cent, developed rheumatic fever. Sixty-seven were given 2.6 grams (40 grains) of aspirin during their hospital stay and after discharge were given the same amount in one dose daily for 3 weeks; 5 or 7.5 per cent, developed rheumatic fever. Seventy-eight were treated with some type of sulfonamide during their hospital stay and for a period of 2 or 3 weeks thereafter; 3, or 3.8 per cent, developed rheumatic fever. It is believed that the series is too small to justify a definite conclusion that sulfonamide therapy was of value in the prophylaxis of rheumatic fever after the onset of a respiratory streptococcal infection. In another study involving patients with scarlet fever caused by either type 17, 19, or 30 streptococcus, conducted in a similar geographical area, the occurrence of rheumatic fever was highest among those treated with large doses of sulfonamides.¹⁶

THERAPY OF ACUTE RHEUMATIC FEVER

Penicillin was administered to 38 patients with acute rheumatic fever in a coöperative study at three Air Force hospitals.¹⁷ The drug was given intramuscularly in doses of 25,000 units at 3 hour intervals for a total of 1,000,000 units. No benefit could be demonstrated in any patient, and definite aggravation of the course of the disease was evident in several cases.

In 1943 Coburn reported his experience with the intravenous administration of salicylate in this disease.¹⁸ This was the first study in which the therapeutic response was correlated with the

TABLE 2
Sulfadiazine Prophylaxis
January 5 to May 1, 1945

actual plasma level of salicylates. The excellent results attained in controlling the infection and in preventing valvular heart disease stimulated further studies.

McEachern at a Colorado field investigated intravenous sodium salicylate therapy, following closely the procedure of Coburn.¹⁹ The intravenous administration was continued until the patient's erythrocyte sedimentation rate dropped appreciably—at least 20 per cent. When this point was reached, oral treatment was substituted, using a total of 10 gm. of sodium salicylate and 5 gm. of sodium bicarbonate daily. This schedule was followed until clinical evidence of active infection had disappeared, and until the blood sedimentation rate remained at normal levels for a period of two weeks. If clinical or laboratory evidence of carditis had been present the salicylates were administered for an additional 2 weeks.

Alternate cases admitted to the hospital wards were treated with oral salicylates exclusively in the dosage as outlined above. Thirty-seven cases were studied in each group. A comparison of results was made on the basis of temperature response, pulse response, joint response, and the time it took the leucocyte count and erythrocyte sedimentation rate to return to normal. The oral method of treatment was more satisfactory in all these comparisons. Blood salicylate levels were obtained in the orally treated group that closely approximated those obtained with intravenous therapy.

The toxic effects of intravenous salicylates were serious and frequent. Six cases developed an acute psychosis. Almost all presented a combination of such symptoms as nausea, vomiting, and tinnitus. This contrasted sharply with the orally treated cases, where fewer than 25 per cent complained of any discomfort, and then usually only mild nausea or tinnitus.

In both groups there was evidence of

valvular injury, as judged by the development and persistence of diastolic murmurs along the left sternal border or loud rough apical systolic murmurs, associated with cardiac enlargement. Five such cases occurred in the intravenous treatment group.

A similar clinical study of salicylate therapy was made at a field in Wisconsin.²⁰ Forty-eight patients received intravenous salicylates and 50 oral salicylates of 10 or more gm. daily; 7 developed significant cardiac murmurs not present on admission to the hospital, or showed progression of preëxisting heart disease. Another group of 88 patients received smaller doses of sodium salicylates, and the blood levels in a few studied cases never reached 300 gamma per ml.; 7 of this group developed significant cardiac abnormalities.

MANAGEMENT OF CONVALESCENT PHASE

A frequent and a major problem, observed during the handling of patients with rheumatic fever, is the development of anxiety states. Many of the contributing factors to these neurotic reactions in the Army have been discussed by Ershler.²¹ In an attempt to minimize these anxiety states, in the fall of 1944 patients were ordered transferred to convalescent centers within 2 weeks of the onset of acute rheumatic fever. This in effect placed the patient under the constant care of only one group of physicians.

In the early part of 1944, Robertson, Schmidt, and Feiring,²² at a convalescent center in Florida were impressed by the large number of cases who on arrival had disabling anxiety neuroses. After personal interviews they believed that the mental state was largely fostered by the preceding therapeutic program, which demanded absolute bed rest throughout, and even beyond the acute stage of rheumatic fever. They challenged the concept that confinement

to bed implies the ultimate expression of rest. These authors define rest as "maximum ease and comfort, physically, mentally, and emotionally. Bed rest ceases to be rest when the patient is no longer at optimum comfort in his environment."

The change in policy in the convalescent program enabled these physicians to treat patients in the acute phase of the disease. Accordingly a group of one hundred patients in this phase were permitted to sit in or out of bed and to walk a short distance to the latrine. The presence of joint symptoms, of changing cardiac murmurs, of varying P-R intervals, of increased erythrocyte sedimentation rates, of subcutaneous nodules or other signs of acute activity were not considered deterrents to limited physical activity. The only exceptions were patients with heart failure or with incapacitating joint inflammations.

Results are admittedly difficult to evaluate, but these patients slept soundly, their appetites were better, as reflected by gains in weight, their bowel habits were more regular, and their morale for recovery was improved. During these first periods of activity the patients were taking therapeutic doses of salicylates. No control cases were observed at the same time for psychological reasons. In this group, however, the clinical and laboratory phenomena indicative of acute rheumatic processes diminished as rapidly as in the previous year when strict bed confinement was practised. At the end of 6 months, no soldier of this group had been discharged from the Army because of an anxiety neurosis.

The final conclusion of the authors is quoted: "We recognize that this study does not warrant any dogmatic conclusions at this time; nor do we advocate indiscriminate physical activity. Nevertheless, it does invite attention for reevaluation of the currently

accepted policy of prolonged bed rest, with its disadvantages, in the treatment of acute rheumatic fever."

SUMMARY

1. Studies at Army Air Forces hospitals during the war lend support to the previous reports of group A streptococcal disease as the inducing infection in acute rheumatic fever attacks.

2. The prophylactic administration of sulfadiazine to large numbers of troops for varying periods of time has not been conclusively shown to lower the incidence of rheumatic fever. Such procedures have caused a prompt reduction in the incidence of hemolytic streptococcal respiratory disease, except in the case of the sulfadiazine resistant type 17 streptococcus.

3. Neither salicylates nor sulfonamides, when administered after the onset of a group A streptococcal respiratory infection and continued for the following 3 weeks, were effective in preventing the onset of acute rheumatic fever.

4. Penicillin in moderately large doses has no beneficial action on the acute rheumatic infection.

5. The use of massive doses of salicylates either intravenously or orally has not protected against the development of valvular heart disease. Blood plasma salicylate levels of more than 300 gamma per ml. are readily attainable by oral administration. Massive doses given intravenously produce severe, though transient, toxic reactions in the majority of cases.

6. A major problem in the convalescent management of rheumatic fever patients is to forestall the development of cardiac neuroses and anxiety states. The present concept of complete bed confinement as true rest has been challenged. It is desirable to investigate further "the value of judicious physical activity as a component part of the therapy of rheumatic fever."

AMERICAN PUBLIC HEALTH ASSOCIATION

Institutions Accredited by the American Public Health Association to Give the Degree of Master of Public Health (Diploma of Public Health in Canada) for the Academic Year 1946-1947

This list is released by the Executive Board of the American Public Health Association as of January 25, 1946, and includes those institutions from which requests for accreditation had been received to that date. Additional applications will be acted upon in due course.

The criteria governing accreditation for the academic year 1946-1947, as approved by the Committee on Professional Education of the American Public Health Association on January 11, 1946, and by the Executive Board on January 25, 1946, follow the listing.

Columbia University School of Public Health
Harvard University School of Public Health
The Johns Hopkins School of Hygiene and Public Health
University of California School of Public Health
University of Michigan School of Public Health
University of Minnesota School of Public Health
University of North Carolina School of Public Health
University of Toronto School of Hygiene
Yale University School of Medicine, Department of Public Health

NOTE: See page 953 of the *American Journal of Public Health*, September, 1945, for Editorial entitled "Accreditation of Schools of Public Health."

MINIMUM REQUIREMENTS FOR INSTITUTIONS TO BE ACCREDITED FOR THE DEGREE OF MASTER OF PUBLIC HEALTH (DIPLOMA OF PUBLIC HEALTH IN CANADA) *

Adopted by the Committee on Professional Education of the American

Public Health Association, January 11, 1946.

The Institution

1. Any institution to be accredited must be a member of the Association of American Universities, or present evidence that it may reasonably be considered as qualified for such membership.

2. The school, faculty, or council administering courses in public health must have such practical autonomy that requirements for the degree are effectively controlled by the public health faculty.

3. The teaching of public health must be under the direction of a full-time teaching faculty, of acceptable quality and experience, which must include (in addition to assistant professors and others of lower rank and in addition to part-time appointees):

- a. One member of professorial grade as director of the school (or department) and at least two other members of professorial or associate professorial grade—all three primarily responsible to the administration of the school, and
- b. At least three other members of professorial or associate professorial grade, either primarily responsible to the school or giving full time to the university and

* These criteria will govern accreditation for the academic year 1946-1947. They may be modified for application after that date; and are likely, in some respects, to be made more stringent. It is the aim of the committee to communicate changes in these criteria to accredited schools at least nine months before the beginning of any academic year.

carrying specific major responsibility for teaching and research in the school. Such a minimum faculty could provide for a body of graduate students in public health, totalling not more than approximately thirty such students.

4. The school or department must have an assured minimum basic annual income adequate for its teaching and research functions and for meeting the various criteria outlined. Such income should be construed to include income from endowment of the school, contributions made from general university funds and grants made over a period of at least five years from sources outside the university. Under the second heading may be included proper allowance for time devoted to instruction of public health students by members of other university faculties.

5. Proper housing must be available, including lecture rooms, seminar rooms, and adequate laboratory facilities for the teaching of subjects in the field of microbiology (including microscopes, culture media apparatus, etc.); for the teaching of vital statistics (including calculating machines for student use, and apparatus for chart making, with tabulating machinery accessible for demonstration purposes); and for the teaching of sanitary engineering (including laboratory facilities for the examination of water and sewage and for the demonstration of the basic principles of hydraulics).

6. Library facilities are essential to the extent of at least 3,000 volumes in the general field of public health (including such special topics as epidemiology, microbiology, vital statistics, sanitary engineering, medical economics and medical sociology, nutrition, and the like), and current periodicals (not including health department reports) to the number of at least 50 in the fields mentioned above.

7. There must be available conveniently located administrative units of public health services, which can be utilized for observation and criticism in the basic courses for the Master of Public Health, and which are of sufficiently high quality to make such observation fruitful.

The Course

8. Candidates to be admitted for the degree of Master of Public Health (Diploma of Public Health in Canada) may be either

- a. Holders of the degree of M.D., D.D.S., or D.V.M. or equivalent degree, from an acceptable institution; or
- b. Holders of a bachelor's degree with adequate training in mathematics and the natural sciences including chemistry and biology; and also qualified in some professional capacity for postgraduate education in public health; and must in addition have either
 - x. Professional academic qualifications in engineering, nursing, education or postgraduate work in other fields of public health; or
 - y. Three years of experience in responsible public health practice.

9. The length of the course shall be not less than one academic year of 32 weeks.

It is highly desirable that the candidate shall have had practical public health experience in the form of supervised field service or in a position involving the exercise of substantial initiative and responsibility. This experience should preferably be obtained prior to entrance into the school. In some schools, candidates not so equipped on entrance are required to complete three months of practical work in the field before receiving their degree.

10. The following courses are among

those generally offered in schools of public health:

- a. Public Health Administration
- b. Sanitation
- c. Microbiology
- d. Vital Statistics
- e. Epidemiology
- f. Physiological Hygiene
- g. Nutrition
- h. Public Health Nursing
- i. Health Education
- j. Economic Factors in Health
- k. Mental Hygiene
- l. Public Health Law
- m. Industrial Hygiene
- n. School Health
- o. Maternal and Child Health

It is believed that it would be highly undesirable to make standard requirements with regard to any particular courses of instruction. It does seem important, however, that the student—at some point in the M.P.H. course (or prior to that course)—shall receive instruction in the following basic fields:

A. Basic Public Health Sciences

- (1) The nature and functioning of the human organism, and the personal behavior which influences its well-being, including nutrition and mental hygiene.
- (2) The nature and behavior of various forms of parasitic life (including viruses); their interaction with the human body as demonstrated by clinical and immunological reactions; the modes in which such micro-organisms are transferred from host to host in the course of their epidemiological history; and the ways in which such dissemination may be controlled.
- (3) The physical environment as it influences health, including not only the classical problems of environmental sanitation, but also those relating to housing and industrial hygiene.

- (4) The social and economic factors which influence the health of the individual and of the community, and the influences of sickness on the social and economic status of the individual and the community.
- (5) The nature and sources of quantitative information bearing on the health of the people, and its numerical presentation and analysis.

B. Public Health Practices

- (6) The principles of applying the basic sciences listed above to community health and welfare. This involves the elements of sound public administration as applied to official and voluntary health agencies, including office management, budget making, personnel relations, and public health law; and includes also the wide field of public relations as influenced by health education and community organization.

11. There must be opportunity for advanced specialization in one or more of the fields listed under (10) above or in such special fields as tuberculosis control, venereal disease control, or tropical medicine. There will be little time available in the M.P.H. year for advanced specialization; but basic work can be conducted effectively only in an atmosphere of advanced scholarship and with the essential stimulus which comes from the conduct of productive research by the faculty and advanced students.

Guarding the Health Department

"The voluntary health agencies, acting in the spirit of our kind of democracy, have often found themselves undertaking to guard the common interest by defending and promoting, and when necessary criticizing, the public health institutions and officials. There is nothing presumptuous in this. It is a proper exercise of the citizen interest in its tax-supported agencies. Such action by citizens or groups of citizens emerges normally out of the major purposes of a voluntary health agency and out of the increasing reliance upon public understanding and public acceptance of new doctrines regarding the prevention of disease and the promotion of health. Such activity may, indeed, be considered an aspect of the educational function of the voluntary health agency and is perhaps exercised too little rather than too much.

"It takes real vision and leadership to see when and where the private

citizens concerned with the health of the community should rally to the defense of their health department, should fight for its standards or for raising the standards, should uphold its unpopular decisions in times of emergencies—and should, on occasion, criticize the administration. The health department which in the past often had its origin in the fear of people in times of great epidemics, is still thought of by some as the disturber of equanimity and the purveyor of dire warnings. It is the task of the voluntary health agencies to develop understanding until the feeling is firmly established in the citizen's mind that the health department is truly *his* health department. The rare health officer can bring this about himself; the average health officer needs the voluntary health agency more often than he realizes."—*Voluntary Health Agencies*. Gunn and Platt. New York: Ronald Press, 1945. 364 pp. \$3.

Public Health Aspects of Dehydrated Foods*

Food and Nutrition Section

DEHYDRATION, as applied to foods, implies the removal of water under controlled temperature and humidity conditions. With this definition in mind, the present report omits fruits, which, with the exception of apples and prunes, are generally sun-dried.¹

The dehydration of foods, particularly vegetables, eggs, and milk, has greatly increased during the present emergency. The past history of the industry, as well as the commercial methods used, have been presented elsewhere,^{1,2} and will not be gone into here. The expansion of the industry, particularly as it pertains to vegetable dehydration, is considered by many as a war measure. Yet at the 1944 annual meeting of the National Dehydrators Association proposals were submitted for an extensive research program to aid in post-war production. What course the industry may take in the future will, of course, depend upon consumer acceptance of dehydrated foods, and the energy and resourcefulness displayed by dehydrators in developing markets and producing quality products. A few surveys have already been made in various cities relative to consumer acceptance of such dehydrated foods as vegetables and soups.^{3,4}

Because of the rapid expansion in production of dehydrated foods, little concerted attention, except in the case of dried egg powder, has been devoted

to their public health aspects. It is the purpose of the committee to examine available data pertaining to the microbiological and nutritional aspects of dehydrated foods, and where advisable to submit recommendations for future action.

The fundamental difference between the bacteriology of dehydrated foods and canned foods is that the former are never sterile. Haines and Elliot⁵ have pointed out that three basic requirements must be met by dehydrated foods to obtain a bacteriologically satisfactory product:

1. Conditions of manufacture must be such that, should toxigenic organisms, e.g., *Clostridium botulinum*, Staphylococci, and perhaps other organisms, be present in, or gain access to the commodity before or during processing, no bacterial toxins are formed.

2. The dehydrated product should not contain organisms likely to be pathogenic to man by the mouth, e.g., *Salmonella* and dysentery bacteria.

3. It is desirable that the general bacterial content of the product shall be reasonably low so that no decomposition or development of undesirable flavor occurs over the period of reconstitution. Special problems may arise if the dehydrated product is to be incorporated into some other food whose water content is high enough for bacterial growth to occur.

Theoretically, groups of organisms whose presence in foods may be considered dangerous include spore-forming anaerobes represented by *Cl. botulinum*; enteric organisms of the typhoid, paratyphoid, dysentery, and *Salmonella* groups; and certain staphylococci. Some epidemiologists would perhaps

* Report of the Committee on Foods (Except Milk).

COMMITTEE ON FOOD (EXCEPT MILK)

Organized 1932. Published reports: *Year Books* 1933-1934, 1934-1935, 1935-1936, 1936-1937, 1937-1938, 1939-1940, 1940-1941, *A.J.P.H.*, July, 1945.

include streptococci. From data available, neither dysentery organisms nor *Cl. botulinum* have ever been found in dehydrated foods but, as explained later, *Salmonella* and staphylococci have been demonstrated. The significance of their presence is complicated by the fact that it is not known whether their number is sufficient to cause symptoms of poisoning. Nor is it known whether *Cl. botulinum* can multiply under conditions prevailing when foods are dehydrated; but as Haines and Elliot have pointed out, the theoretical possibility cannot be dismissed.

Aside from the microbiological aspects of dehydrated foods and their relation to public health, the possible loss of nutrients during processing cannot be overlooked. Considerable data have accumulated in this field relative to dehydrated vegetables and eggs, but there is a paucity of information in the case of dehydrated fish. Few data are available indicating the loss of nutrients by rehydration of dehydrated foods.

DEHYDRATED VEGETABLES

There has been a tremendous increase in the production of dehydrated vegetables during the present emergency (Table 1).

As of July 1, 1944, approximately 30 per cent of the entire production came from California; 18.5 per cent from Idaho, practically all of which was potatoes; 6 per cent from New York; Washington 5.5 per cent; and 5 per cent each from Maine and Oregon. The remaining 30 per cent originated among the other states of the country.

Microbiological aspects—Because of their proximity to the ground, vegetables are liable to contamination by soil bacteria, as well as infection from human sources by handling during preparation for dehydration. Washing and subsequent blanching will reduce the flora, but recontamination will occur during trayng and packing.^{6,7}

Prescott⁸ and Prescott, Nichols, and Powers⁹ were probably the first to make a bacteriological study of dehydrated vegetables 25 years ago. They found none of the vegetables investigated to be sterile, and practically all the organisms found were of the soil and water type, the latter predominating.

² Not available.

³ It was reported that 6 dehydrating plants were operating before 1940, and that only 4 of these were of importance.

⁴ Approximate.

⁵ Estimated.

⁶ Preliminary.

Agar plate counts ran from 60 to 1,600,000 per gm.; while mold counts varied from less than 20 up to 600 per gm. In laboratory tests Prescott inoculated stringless beans, parsnips, tomatoes, and spinach with pure broth cultures of *Bacillus coli*, *B. typhosus*, *B. paratyphosus* A and B, *B. enteritidis*, *B. paracoli*, *B. subtilis* and *B. welchii*. The vegetables were dehydrated at 80° C. (176° F.) for 4 hours. *B. subtilis* was found to have survived dehydration, while organisms resembling *B. typhosus* and the paratyphoid forms in some respects, but not typical, were found. Further work under commercial conditions of dehydration showed destruction of all or-

TABLE 2

Occurrence of Bacteria in Dehydrated Vegetables (Condensed from Haines and Elliot)

<i>Product</i>	<i>Plate Count, Organisms per gm.</i>	<i>Flora</i>
Carrots	1,000 to 100,000,000	Micrococci, white non-hemolytic coccus, sporing aerobes, molds, <i>actinomyces</i> , coliforms of the aerogenes and fecal types. Clostridia and thermophiles only occasionally.
Cabbage	1,000 to 1,000,000	Micrococci, coliform (aerogenes and fecal), sporing aerobes, enterococci, <i>viridans</i> streptococci, small Gram-positive rods. Clostridia and thermophiles occasionally.
Potatoes	100 to 1,000,000	Sporing aerobes, white and yellow micrococci, coliform (chiefly <i>aerogenes</i>), diphtheroids, Gram-negative white cocci, <i>actinomyces</i> and molds. Clostridia and thermophiles occasionally.

ganisms with which the material had been inoculated. Prescott points out that these results should be considered only preliminary. Later researches by Clague¹⁰ showed that dehydration will not completely kill *B. coli* if present.

Although there has been some research carried out in this country since Prescott's report^{6, 7, 10, 11, 12} on the bacteriology of dehydrated vegetables, more must be accomplished before a clearer picture can be obtained. Recent data summarized from researches of British investigators by Haines and Elliot⁵ are given in Table 2.

Vaughn, Stadtman, and Kueneman⁶ have surveyed a number of dehydration plants to determine the microbial population of the finished products. They found that overloading of the trays contributed to a large bacteria count in the finished product. Other factors influencing the count were post-blanching contamination by unclean hands of the workers, dirty trays and other inadequately cleaned equipment, and the use of polluted water. They found counts as high as 1,000,000,000 per gm. in spoiled, dehydrated potatoes, the most predominant types being the non-spore formers *Acrobacter aerogenes* and spore formers similar or identical to *Bacillus megatherium*. In soured dehydrated

onions, lactic acid organisms tentatively identified as *Lactobacillus plantarum* and *L. brevis* were found along with coliform organisms. Both Clague¹⁰ and Kinter and DeLay¹¹ found lactose fermenters not of the coliform type in dehydrated vegetables. Hucker, et al.⁷ also found lactic acid and spore-bearing rods in two dehydration plants studied.

Hucker, et al.⁷ carried out studies in 12 dehydration plants and of dehydrated potatoes, beets, and carrots. In 9 of these 12 plants the food was contaminated with members of the coliform group. In approximately 80 per cent of the cases, presumptive tests could be secured for coliform organisms on the finished dehydrated vegetables just prior to final packaging.

There are no bacteriological standards for dehydrated vegetables. The Quartermaster Corps controls the quality of its dehydrated products by means of specifications, plant supervision, product inspection, and laboratory examination.¹³ It should be pointed out that these specifications do not include bacteria counts, but are chiefly physical. In some cases, special sanitary inspections are carried out by personnel of the Veterinary Corps at the request of the procuring agencies.

The moisture content at which de-

hydrated vegetables are dispensed would probably not permit bacterial growth. If properly protected from moisture pick-up, Prescott, Nichols, and Powers indicate that bacteria in the product will decrease during storage.⁹ Kinter and DeLay¹¹ found that dehydrated cabbage having an initial count of 1,058,000 decreased to 10,000 upon 10 weeks' storage. Vaughn, et al., on the other hand, state that unpublished data by them indicate that under ideal storage conditions the microbial population may persist for long periods with little or no decrease in numbers.

Nutritional aspects—The nutritive value of dehydrated vegetables will depend upon the quality of the raw product, speed and care in handling, method of blanching, and rapidity of dehydration.

There will be some loss of minerals, proteins, and water soluble vitamins during blanching, and in general this loss is greater in water blanching than in steam blanching.¹⁴⁻¹⁷ In the United States, the majority of vegetables are steam blanched. Doty, et al.¹⁸ have reported no loss of calcium or phosphorus during blanching of carrots.

Improvements have been attempted in methods of dehydration with the purpose of enhancing appearance, palatability and vitamin retention. Perhaps the most recent innovation has been dehydration in natural gas or methane. It is claimed that retention of vitamin C is greater using this method than when carried out in air.¹⁹ Tiller, Litkenhous, and Tuberville²⁰ have experimented with infra-red dehydration. Considerable work has been done on the use of sulfur dioxide to retard deterioration of dehydrated potatoes and cabbage. Sulfur dioxide also aids in preserving vitamin C potency, but destroys thiamine.

Morgan, et al.¹⁵ in a study of limited scope, found vitamin losses in blanching and dehydrating vegetables in com-

TABLE 3

Losses of Vitamins in Commercially Produced, Freshly Dehydrated Vegetables (Condensed from data of Morgan, et al.)

(Expressed as per cent of the content of corresponding fresh samples)

	Per cent Loss in		Cumulative
	Blanching	Dehydrating	Loss Per cent
Niacin	0-33	0-30	0-33
Pantothenic acid		0-30	0-30
Thiamine	0-37	11-38	0-56
Ascorbic acid	0-25	0-71	0-83
Riboflavin	0-10	0-30	0-30
Carotene	3-15	14-31	0-40

mercial practice as shown in Table 3.

In the light of present information it can be said that losses of vitamins, especially ascorbic acid and thiamine, during the commercial production of dehydrated vegetables, are large, and this factor will be of importance if such foods become an essential part of the diet.

A knowledge of the vitamin content of dehydrated foods is of importance where nutritional evaluation is desired, but the usefulness of published data is questionable unless the age of the sample at the time of analysis is indicated. Pavcek and Elvehjem²¹ have published such data, but unfortunately the age of the samples is not stated.* Morgan, et al. have compiled similar data and, although the samples analyzed are limited, their age at time of analysis is stated.

During the storage of dehydrated foods there is a loss of vitamins. Extensive research has been undertaken by many investigators in the attempt to decrease this loss by improved packaging and sealing in an inert gas. The most recent report has been that by Neuman, Wilson, and Van Wazer, Jr.²² Heberlein and Clifcorn²³ found that an inert atmosphere favored the

* The committee has been informed (private communication) that the samples were analyzed "within a few months after dehydration."

retention of carotene and ascorbic acid when dehydrated vegetables were stored at room temperatures, but the protective action of an inert gas was greatly reduced with increased storage temperatures. An inert gas had no significant effect on thiamine or riboflavin retention. Riboflavin appears to be quite stable in dehydrated vegetables. Increased storage temperatures favored the destruction of ascorbic acid, thiamine, and carotene. Beardsley, Prindle, and Stevens²⁴ also found that packing in an inert gas favored the retention of ascorbic acid and carotene, while it had no effect on the thiamine content. These investigators found no consistent effect of temperature on the stability of carotene. Tressler, et al.,¹⁶ on the other hand, reported relatively large losses of carotene at all storage temperatures above -40°C . (-40°F). Doty, et al. found that dehydrated carrots stored at 21.1°C . (70°F .) in glass containers showed considerable loss of carotene, while there was little loss at a storage temperature of 17.7°C . (62°F .) and at 4.4°C . (40°F).

The effect of lower moisture content of the dehydrated vegetables on retention of vitamins has been investigated. Chace²⁵ believed that low moisture content favored decreased loss of carotene and ascorbic acid during storage. Tressler, et al.¹⁶ also shared this belief, but Heberlein and Clifcorn²³ found that, with the possible exception of decreasing the thiamine content of cabbage, the additional drying of beets, cabbage, and carrots to a lower moisture content than customarily attained had no significant effect on the vitamin content before or after storage.

Although dehydrated vegetables may contain significant quantities of vitamins when they reach the consumer, improper preparation for the table will cause appreciable losses. Fenton and Barnes²⁶ found that excessive quantities of cooking water caused a marked

decrease in the amount of thiamine retained in the vegetable, due to the leaching action. Whether or not the vegetable was rehydrated before cooking, time of rehydration and rapidity of cooking all had an important bearing upon retention of water-soluble vitamins.

DRIED EGG POWDER

Although dried egg powder was produced before World War II, output has greatly increased during the war period, chiefly to satisfy military and Lend-Lease demands.

TABLE 4

Dried Egg Production in the United States¹

¹ Bureau of Agricultural Economics, U. S. Dept. Agr.

Microbiological aspects—Hartsell²⁷ has listed the factors largely responsible for the presence of bacteria in dried egg powder as:

1. Number and kind of bacteria in the liquid whole egg
2. Temperature of processing and storage
3. Activity of lysozyme
4. Whether or not the eggs are pasteurized before breaking
5. Evenness and method of drying
6. Moisture in the finished product

Two of the factors listed: namely Nos. 3 and 4, could perhaps be omitted because some investigators see no reason for assuming the activity of lysozyme, and eggs are not pasteurized before breaking, nor has such a technique been used in the past.

Bacteria specifications, which at present should be considered as tentative, have been established for the purchase of dried egg powder by certain

government agencies. The specifications of the War Food Administration require that the plate count should not be in excess of 300,000 per gm., and *Escherichia coli* should not be present in 0.001 gm.²⁸ The Quartermaster Corps' tentative specifications permit a maximum plate count of 200,000 per gm. and a yeast-mold count of not more than 100 per gm. Higher counts are accepted with a penalty.²⁹ In 1943 the British Ministry of Food established standards for Grade A and Grade B powder³⁰:

Grade A powder (prime powder for use in fresh egg dishes)—total viable count after 48 hours incubation at 37° C. shall not exceed 500,000 per gram, with *E. coli* absent from 1/100 gm.

Grade B powder (residual fractions, for baking purposes only)—no limit for viable count, but *E. coli* absent from 1/1,000 gm.

These standards were modified for the 1944 season in that determination of coliform organisms and *E. coli* in Grade A powder was dropped.

Gibbons and Fulton³¹ and others have pointed out that the number of bacteria present in dried egg powder gives some indication of the sanitary conditions prevailing in the breaking and drying plants. In this connection it is interesting to note that more recent researches indicate that direct counts rather than plate counts reflect more accurately the conditions under which the eggs were handled.^{34, 35} Gibbons and Moore³² state that there is little relationship between total viable count, coliform and *E. coli* content and the presence of *Salmonella* organisms.

Considerable research has been accomplished on the bacterial flora of dried egg powder, particularly the presence of organisms of the *Salmonella* group, and their relation to public health. Unfortunately much of the work on *Salmonella* remains unpublished. *E. coli* has been found by numerous workers, and Stuart, Hall,

and Dicks state that organisms of the coliform group remain viable during storage of the product.³³ Reports have been made by British investigators⁴² of the presence in dried egg powder of coagulase-positive staphylococci, viridans streptococci, and hemolytic streptococci; *S. albus*, *Proteus*, *coli* (most often aerogenes, but sometimes fecal) pink, yellow, and white micrococci, sarcinae, diphtheroids and other small Gram-positive rods, *Clostridium sporogenes*, and *Cl. welchii*. Enterococci were of frequent occurrence.

The organisms of greatest pathogenic significance are *Salmonella*, hemolytic streptococci, and coagulase-positive staphylococci. However, Gibbons and Moore³⁶ state "Whether the contamination of egg powder with organisms of the *Salmonella* group can be regarded as a health hazard is debatable." Organisms of the *Salmonella* group have been reported in dried eggs by numerous investigators.^{32, 37, 38} Experiments by Gibbons and Moore³⁶ have shown that 99 per cent of the *Salmonella* in liquid egg are killed during spray-drying where the air inlet temperature is 121° C. (250° F.) and the air outlet temperature is between 60° and 66° C. (140°–150° F.). The greater the initial contamination, the greater the survival upon drying. It should be pointed out that this work was not done under plant conditions.

Salmonella may be introduced into dried egg powder by human carriers or by contaminated eggs. In this connection it should be pointed out that there is no known case of *Salmonella* being introduced by human carriers. Mallman, Ryff, and Matthews³⁹ have reviewed the literature of the large variety of types of *Salmonella* which have been found to occur in the common fowl. They themselves isolated 11 different species of *Salmonella* from the intestinal content or feces of chickens. In spite of the large amount of work

undertaken, the source of *Salmonella* in dried egg powder apparently remains unknown. Recent studies by Gibbons and Moore³⁶ gave considerable evidence that eggs were the source of the organism.

Gibbons, Moore, and Fulton⁴⁰ have investigated the growth of the *Salmonella* group and of *Staphylococcus aureus* and four strains of *Streptococcus pyogenes* in liquid and reconstituted eggs. Group A streptococci did not grow in liquid egg and the investigators point out that this is probably one explanation why they are not usually found in egg powder. *Salmonella* organisms and *Staphylococcus aureus* grew under proper temperature conditions and incubation periods, but in commercial practice the danger would be remote under adequate bacteriological supervision.

If reconstituted eggs are allowed to stand overnight there would be danger of multiplication. Work by Haines and Elliot⁵ indicates that for this reason the reconstitution period should not exceed 4 hours.

The British Ministry of Food has suspected that dried eggs might be responsible for *Salmonella* food poisoning in Britain.³⁰ Every epidemiologist is aware of the difficulties connected with obtaining conclusive evidence of the source in cases of food poisoning, and no convincing evidence has been presented to justify the suspicion that dried whole egg powder might be responsible for *Salmonella* food poisoning. In this connection, Gibbons and Moore³² state that eggs have not been incriminated in *Salmonella* poisoning. However, on June 11, 1945, the British Ministry of Food issued an order⁴¹ to control the use of dried eggs in specified manufactured foods with the object of avoiding potential cases of food poisoning.

In general, bacterial flora in dried egg powder decrease during storage if

the humidity is not excessive. Tracy, et al.⁴³ and Hartsell²⁷ have shown that the bacteria count of the powder decreases as temperature and storage time increase. For instance, Tracy and his coworkers found that dried egg powder stored at -20.5°C . (-5°F .) had a higher count per gram than that stored at 32.3°C . (90°F .), even after a period of $1\frac{1}{2}$ years. Gibbons and Fulton³¹ showed that dried egg powder stored at 55°C . (131°F .) was practically sterile in 4 weeks. In this connection, it is interesting to note that Stuart, et al.⁴⁴ found that at a temperature of 30°C . (86°F .) and below, bacterial death in dried whole egg powder of sanitary quality proceeded at a uniform logarithmic rate normal for bacterial population of material stored in a dry condition.

As for the death of specific organisms during storage of dried egg powder, Stuart, Hall, and Dicks³³ state that organisms of the coliform group remain viable during storage. Gibbons and Moore³⁶ showed that *Salmonella* organisms surviving dehydration operations die off during storage even at low temperatures. Haines and Elliot⁵ reported that a coagulase-positive strain of *S. aureus* died out slowly at room temperature in whole egg powder.

Bacterial population is related to the moisture content of the dry egg powder. Haines and Elliott⁵ state that bacterial growth is unlikely in egg powder containing less than 15 per cent moisture, and mold growth below about 10 per cent moisture content. Gibbons and Fulton,³¹ on the other hand, found that at 5 per cent moisture levels there was an increase in molds. Stuart, Hall, and Dicks³³ reported that when the moisture content is 5 per cent or less, bacterial death appeared to be greater as the moisture content was reduced.

The temperature at which eggs are dried is an important factor in determining the quality of the product;

the lower the drying temperature, the better the physical qualities, but the greater the survival of bacteria. Thus, Gibbons and Fulton³¹ have shown that a decrease of from 4° to 15° C. (39°–59° F.) in the temperature of the exhaust air from a spray dryer is accompanied by a 3 to 5 fold increase in the number of bacteria in the resulting powder.

Rapid cooling of the product after drying is desirable from the standpoint of physical quality. Johns³⁰ and Gibbons and Fulton³¹ have pointed out, however, that such a technique means a higher bacterial count.

In some instances where liquid egg is pasteurized by passing through a pre-heater before spray drying, significant increases in bacterial population have resulted. Johns³⁰ investigated this and found that in such cases material had adhered to the walls of the pre-heater tubes, setting up a nucleus of infection. At temperatures less than 57.2° C. (135° F.) in preheaters multiplication of organisms will take place and for that reason pasteurizing temperatures of 60°–62.8° C. (140°–145° F.) are used. Tube heaters cannot operate at these temperatures and are not used in the United States.

Nutritional aspects — Bate-Smith⁴⁵ found that there was little loss of vitamin A by spray drying, but that there was a loss when eggs were tray dried. Hauge and Zscheile,⁴⁶ Hauge, Zscheile, Carrick, and Bohren,⁴⁷ Klose, Jones, and Fevold,⁴⁸ and Cruickshank, Kodicek, and Wang⁴⁹ obtained similar results with spray-dried egg powder. Bate-Smith, and Klose, et al. found that spray drying caused no loss of thiamine. The results of the work of Klose and his coworkers indicated that riboflavin, pantothenic acid, and niacin suffered no loss by spray drying.

Storage of dried egg powder brings about a loss of vitamins. Hauge, et al. found that the greatest losses of vitamin

A occurred in powder held at room temperature, such losses amounting to 40 per cent in 12 months. Warehouse storage caused a loss of 30 per cent. Klose, et al. reported greater losses at comparable temperatures. Low storage temperatures increase vitamin A retention. Cruickshank, et al.⁴⁹ found no loss of either vitamin A or D during storage in a nitrogen pack at 15° C. (59° F.) for 5 months.

Klose, et al. have found pantothenic acid and niacin to be quite stable during 9 months' storage. There was a slight destruction of riboflavin at storage temperature of 37° C. (98.6° F.) but essentially none at lower temperatures. Thiamine was found to be stable at storage temperatures of –9.4° C. (15° F.), but half of the potency was lost when the material was stored at 37° C. (98.6° F.) for 9 months. Cruickshank, et al. have shown that it is storage temperatures rather than high moisture content of the powder which detrimentally affects the retention of thiamine. There is an apparent inhibition of losses of vitamin A after 3 months' storage, for the rate of loss in Klose's work was greatest during the first 3 months, after which vitamin A seemed rather stable.

There is a paucity of data regarding the nutritive value of reconstituted egg powder. Herraiz and Herrero⁵⁰ report reconstituted dried eggs to be a good source of vitamin A, thiamine, riboflavin, and niacin.

DEHYDRATED FISH

Dehydrated fish should not be confused with salted, dried, or smoked fish. The former is prepared by steaming and grinding the fish and removing moisture under controlled conditions of humidity and temperature. During dehydration the fish may or may not be smoked. So far as known, fish is not at present being commercially dehydrated in the United States. In 1944

a plant was erected on the west coast of southern Florida for dehydrating mullet, but never got into commercial production. Some experimental work has been undertaken in the United States relative to fish dehydration,⁵¹ but most of the research has been carried out at the Torry Research Station in Aberdeen,^{52, 53} and by the Fisheries Research Board of Canada. Nearly all the work of the latter agency remains unpublished.

Microbiological aspects—Unpublished data by Shewan⁵⁴ indicate that pathogens of the food poisoning type are not usually present as a part of the normal flora of fish. During handling aboard ship the flora will be subject to change, but Shewan believes it unlikely that pathogenic cocci will be present in other than small numbers at this stage, since low temperatures brought about by icing are unsuitable for their growth. During subsequent handling for dehydration, the flora will again change, and may consist predominantly of cocci, of which from 15 to 30 per cent may be coagulase-positive *S. aureus*. From the standpoint of public health, therefore, it is important that the fish be thoroughly cooked prior to dehydration and that dehydration be carried out rapidly and at sufficiently high temperatures to prevent bacterial contamination or growth. The Torry Research Station at Aberdeen has pointed out that the standard hygiene in the dehydration of fish should be more like that of a modern dairy than that of the salt fish curing yard or fish meal factory; and that all steps in the processing should be carried out under competent bacteriological supervision.

According to Tarr,⁵⁵ unless dehydrated fish (containing 40 per cent fat) is stored at humidities less than 75 per cent (at temperatures of between 68° and 99° F.), mold will develop. Mold growth is unlikely unless the

relative humidity is 80 per cent or more, which corresponds to a moisture content of 17.5 per cent. At this moisture level, mold growth will be slow and limited. At 85 per cent relative humidity (corresponding to a moisture content of 19.5 per cent), bacteria will increase.

There are no bacterial standards in the United States for dehydrated fish. A Lend-Lease contract in 1944 specified a plate count of not more than 10,000 bacteria per gm. On the basis of research at Torry,⁵⁶ it was believed that, so far as dehydrated cod and haddock were concerned, a good product should not have more than 10,000 organisms per gm.

Nutritional aspects—Few published data are available relative to the vitamin content of dehydrated fish. Stansby⁵⁷ carried out feeding tests with rats on dehydrated cod, mullet, whiting, and carp and found that the dehydration process caused a loss of about 50 per cent of the thiamine and 65 per cent of the riboflavin. This loss took place largely in the cooking process and about half of each vitamin lost could be recovered in the "stick."

Martinek and Jacobs⁵⁸ have investigated the apparent digestibility of protein from dehydrated fish when fed to rats at a level of 9 per cent by weight in the basal diet. All the dehydrated fish investigated (cod, mullet, whiting, and carp) had an apparent digestibility of about 87 per cent. Stansby⁵⁷ also found that the dehydration process did not adversely affect either the nutritive value or the digestibility of the fish.

DEHYDRATED MEAT

The dehydration of beef and pork in the United States has been primarily a war measure. Accurate production figures are impossible to obtain, but purchases by the government reflect approximate production because dehydrated meat is not available for civilian use. From October to Decem-

ber, 1942, dehydrated pork purchases amounted to 1,264,720 lbs.; 1943, 16,450,536 lbs.; and in 1944, 11,992,409 lbs. No figures are available for dehydrated beef.

Microbiological aspects—There are no bacteriological standards in the United States for dehydrated meat. Specifications do, however, require a standard precooking treatment of "a minimum of 30 minutes at not less than 165° F. internal temperature."⁵⁹ The provisional bacteriological standard adopted by the Ministry of Food Advisory Bacteriological Committee states⁵⁶ "Conditions of manufacture shall be such that bacterial toxins are not formed. The dried product shall not contain organisms likely to be pathogenic to men by mouth, and shall have a bacterial content, as estimated by a 48 hour plate count at 37° C. on nutrient agar, not exceeding 10,000 per g." These specifications are in effect for all dehydrated meat now obtained by the British. The workability from a routine control standpoint of the provisions that the product "shall not contain organisms likely to be pathogenic to men" will undoubtedly be questioned by many American bacteriologists. Nevertheless, English workers are examining the meat for pathogens as a routine procedure.

According to researches by Haines and Elliott,⁵⁷ raw meat may carry a flora consisting of *Achromobacter*, cocci, coliform and *Proteus* organisms, and aerobic spore formers. These organisms will be destroyed by adequate steaming of the ground meat prior to dehydration. During subsequent tray-drying and dehydration, the bacterial count will again increase. Hankins, et al.⁵⁸ found that bacterial spores, although few in numbers, were the predominating microorganisms found in the dehydrated product. Gas-forming bacteria whose optimum growth was 37° C. (98.6° F.), and putrefactive

anaerobic bacteria were also found. Haines and Elliott could not find pathogenic organisms or *S. aureus* in their dried product. Their investigations in this respect were, however, limited.

It is quite likely that danger from food poisoning bacteria in dehydrated meat is controlled chiefly by the moisture content of the product, and so long as the moisture content remains at 10 per cent or below in any part of the product, the problem of bacterial food poisoning is probably nil. If dehydrated meat has a moisture content of less than about 15 per cent (calculated on a fat-free basis) microorganisms cannot develop.⁶⁰ Hankins, et al. found that food poisoning strains of *Staphylococcus* and *Streptococcus* failed to grow in the meat if the moisture content did not exceed 20 to 30 per cent. *Salmonella* did not grow in meat containing 50 per cent or less of moisture. *Clostridium botulinum* toxin formation occurred only in meat containing 30 per cent or more moisture. Some evidence was obtained that an increase in storage time and temperature had a tendency to increase the potency of the toxin developed later from surviving spores if they had the opportunity to function.

The above data imply that in the rehydration of meat there is apparent danger of food poisoning, if such rehydration is prolonged. It has been found that toxin formation from *Cl. botulinum* will take place in from 8 to 10 hours in reconstituted meat if spores are present in the dehydrated product.⁵⁹ Bate-Smith⁶⁰ states that the reconstituted meat should not be allowed to stand for more than an hour or two before being cooked.

In general, there is a decrease in the population of bacteria during storage. Experiments by Haines and Elliot suggest that the death rate of a coagulase-positive strain of *S. aureus* was slower in nitrogen than in air, and more rapid

at 37° C. (98.6° F.) than at 15° C. (59° F.). In this particular instance no significant difference was found between the rate of death at 2.0 and 4.5 per cent water content in air at 15° C. (59° F.). Hankins, et al. found that mold growth seldom took place on dehydrated meat containing less than 15 per cent moisture and that mold grew only with difficulty on fat meat.

Nutritional aspects—Hankins, et al. showed that during storage of dehydrated meat, particularly at high temperatures, there is an apparent breakdown of the proteins accompanied by a change in color and flavor. Such changes decrease the palatability. These workers also found the digestive coefficient of dehydrated pork to be 92 per cent, of dehydrated beef 88.7 per cent, and of dehydrated mutton 90.9 per cent, as compared to 80.3 per cent for dried skim milk and 89.4 per cent for dried eggs. Rice and Robinson⁶¹ report that the protein quality is not significantly reduced during dehydration.

Poling, Schultz, and Robinson⁶² state that the biologic value of the proteins of dehydrated beef and pork was not significantly below that of the raw commodity when fed at 18 per cent protein levels.

Hankins, et al. found relatively small losses of riboflavin and niacin during dehydration, but losses of thiamine amounted to about 50 per cent. Poling, et al., on the other hand, found a retention of thiamine and pantothenic acid ranging from 76 to 63 per cent, while retention of riboflavin amounted to 90 per cent. These results were confirmed by Rice and Robinson⁶³ who report a 76 per cent retention of thiamine, a 92 per cent retention of niacin, and 68 per cent retention of pantothenic acid in dehydrated beef. Pork retained 63 per cent thiamine, 92 per cent niacin, and 73 per cent pantothenic acid during dehydration. There was no

loss of riboflavin in dehydrating either beef or pork.

During storage, loss of thiamine is quite rapid. Rice, Beuk, and Robinson⁶⁴ found that only 15 per cent was retained after storage for one week at 48.9° C. (120° F.). Hankins, et al. have reported complete destruction in 8 weeks at 43.4° C. (110° F.). Losses are less at lower temperatures. This confirms the findings of Rice and Robinson⁶¹ who reported a 29 per cent retention of thiamine in pork stored at 26.7° C. (80° F.) for 219 days, but complete destruction at higher temperatures. Rice, et al.⁶⁵ found that the loss of thiamine in dehydrated pork was roughly proportional to the moisture content between 0 and 6 per cent moisture levels. There was a rapid loss at storage temperatures above 37° C. (98.6° F.). At 3° C. (37.4° F.), the loss was about 4 per cent.

There appear to be insignificant losses of niacin after 9 months' storage even at elevated temperatures.⁵⁹ Rice and Robinson⁶¹ report little or no loss of niacin, riboflavin, or pantothenic acid in dehydrated pork or beef stored for 219 days at 37.2° C. (99° F.). Above storage temperatures of 48.9° C. (120° F.) there was a slow loss of riboflavin and pantothenic acid.

Although the packing of certain dehydrated vegetables in an inert gas aids in retention of certain vitamins, this does not seem to be the case with dehydrated meats. Rice, et al., for instance, found that vacuum-nitrogen or carbon dioxide packing did not increase thiamine retention during storage.

So far as can be determined from published reports and private communications, there have been no cases of food poisoning arising from the consumption of dehydrated foods. Nevertheless, *Salmonella* and *Staphylococci* have been found in certain types of dehydrated foods, and it is believed that foods containing such organisms

should be considered potential vectors of food poisoning.

It is recommended that the committee consider the advisability of establishing bacterial standards for dehydrated foods, particularly for dried egg powder. If it is desired to establish such standards, it will be necessary to determine whether a plate count or total microscopic count, along with an examination for the absence of groups of organisms likely to be pathogenic, would be advisable in all classes of dehydrated foods under consideration. It is believed that the most effective procedure for determining the advisability and necessity of establishing standards would be by means of a symposium at the Annual Meeting of the Association.

Teamwork for Industrial Health*

J. J. BLOOMFIELD, F.A.P.H.A.

Senior Sanitary Engineer, Industrial Hygiene Division, Bureau of State Services, U. S. Public Health Service, Bethesda, Md.

LIKE most thoughtful citizens, I am sure that you have been thinking a good deal of the atomic bomb. Even though we may not fully understand the significance of our progress in the new science of atomic energy, we do know that we stand on the threshold of a brand new civilization. Once we accept this idea we can begin to act constructively. We can begin to plan.

Now you will probably ask yourself just what the atomic bomb has to do with industrial health. I am sure that you will agree that whatever affects society as a whole affects industrial health, especially in a highly industrialized country such as ours. The atomic bomb was made possible only through united action. Indeed, the "secret" of the atomic bomb was the coördination of all resources—scientific, industrial, and governmental. This is really the great lesson of the war in relation to industrial and community health. Science produces "miracles" *only* when it is applied. The medical and health sciences have never yet been applied in the intense and coördinated way that produced the atomic bomb. We really do not know as yet what "miracles" of health our scientific knowledge could produce if we applied it universally.

Even when used in a meager way, the health sciences produce remarkable results in increased efficiency of the human machine, in more harmonious re-

lationships, especially between labor and management, and in a greater capacity for earning, as well as in the saving of life and the promotion of health. Let me give you just one example of what the application of our present scientific knowledge can accomplish in the field of industrial health alone.

Early in 1941, at the beginning of our defense program, the War Department placed the joint responsibility for the organization and maintenance of industrial health services in the large government-owned munitions plants upon the Army Medical Corps and the Industrial Hygiene Division of the U. S. Public Health Service. Since many of the plants were at that time still in the process of construction, it was possible to begin planning for a good industrial health program at the blueprint stage. The health program in the munitions plants was carried out for the entire duration of the war. Through frequent inspections, our professional staff saw to it that safe and healthful working conditions were maintained and that the workers obtained the benefits of the best practices in the field of personal hygiene. As a result, outstanding success was achieved in the reduction of health and accident hazards in this vital industry. Disability and death rates from exposure to toxic explosives and related chemicals have been gratifyingly low. [See note on page 268.]

* Presented before the Kingsport Safety Council meeting, Kingsport, Tennessee, September 14, 1945, and before the Women's Group Action Council, Winston-Salem, North Carolina, October 9, 1945.

ELEMENTS OF AN INDUSTRIAL HEALTH PROGRAM

We have known for some time that if

we are to maintain and improve the physical and mental well-being of our workers we must not only be concerned with the working environment but also with conditions outside the workplace. We know that efforts to insure a safe and healthful working environment may often be nullified by unfavorable conditions in the community. That was brought forcefully to our attention in many dramatic incidents during this war. Let me give you just one instance which will illustrate my point.

At the very height of the war, I happened to be on the West Coast visiting the health department of a state which was active in the production of all types of fighting ships. At the time of my visit, there was an outbreak of dysentery in a small shipyard employing 8,000 workers. About 10 per cent of the working force, or 800 persons, were affected. Those workers not sick were on the point of walking out on strike unless something was done to control the situation. The source of the trouble was easily found. The old septic tank, designed to serve about 500 people, had overflowed and was discharging the sewage from 8,000 people into a lake, on the shores of which the yard was situated. Through some mishap, probably a cross-connection, polluted lake water was siphoned back into the shipyard drinking water—results, 800 sick workers, some of them in the hospital. Failure of the community to provide adequate sewage disposal facilities was the true cause of the outbreak.

I think this one example clearly illustrates that the health of industrial workers is a matter of concern not only to industry but to the community at large. In dealing with the worker, therefore, we must adopt a concept of "the total man," if we are to keep him on the job and enable him to contribute to the life of the community his utmost in healthful living and intelligent citizenship.

If we accept this concept concerning the industrial worker, then we must provide at least the elements of a good industrial health program. Broadly, the program aims to achieve and maintain three goals: (1) a safe and healthful working environment; (2) a healthful community environment; and (3) healthy, well adjusted men and women engaged in industrial production. To accomplish these purposes, four types of services are needed.

First, the provision of a safe and healthful working environment. This involves study of actual and potential hazards to determine the danger from poisonous dusts, gases, and fumes. Processes and materials may have to be changed to safeguard workers, or special equipment provided. Sanitation in the plant is equally necessary.

Second, the provision by industry of medical and nursing services and a properly equipped dispensary. First aid treatment of illnesses and accidents was the original function of industrial medical departments—a service made necessary by state workmen's compensation laws. These services in the larger industries now have been expanded to include preplacement examinations for applicants. The importance of this examination is increasing, because the placement of large numbers of handicapped persons requires that the worker be carefully fitted to his job. The medical departments in large industries have further broadened their scope to provide a continuous preventive program including periodic health examinations, which vary in frequency and type according to the requirements of the job. In small plants, where a full-time medical service is not feasible, part-time services may be obtained from private practitioners of medicine, and an industrial nurse may be employed full time. To supplement the medical service, large industries are also employing dentists to give emergency

treatment and regular dental examinations. In the majority of industrial medical services, patients are referred to private physicians and dentists for complete treatment when the illness is not related to the job. A health education program organized coöperatively by the medical and personnel departments in coöperation with the employees is another feature of a complete plant program.

Third, the provision of feeding facilities for workers on all shifts, assuring them of adequate, inexpensive meals.

A fourth essential may be called welfare services. These include mutual benefit plans, Blue Cross hospital insurance plans, and other methods for the purchase of medical service by workers and their families. Counseling services to help individuals solve their personal problems, organization for recreation, and other activities that contribute to morale and healthful living may be included.

Your state industrial hygiene service is specifically designed to help reduce industrial disability resulting from conditions of employment. As you all know, however, the major share of industrial disability, nearly 90 per cent of the total, is due to common ailments, such as colds, digestive diseases, and certain chronic disorders which do not necessarily originate from employment. These problems must be attacked where people work as well as where they live. Only by intensive effort on the part of all public health agencies, the medical profession, industry, and labor, shall we reduce the waste of life, money, and productivity. Small industries are especially in need of such coördinated effort, for they are unable to provide these basic services by themselves.

AVAILABLE RESOURCES FOR INDUSTRIAL HEALTH

Accomplishing the objectives of the program I have just outlined, calls for

teamwork. All available resources must be put to work. It is just plain common sense that no one organization is ever going to obtain optimum health and safety single handed. The complexity of services, equipment, facilities, and personnel needed to translate a blueprint into healthier men and women proves the point. The use of available resources obviously requires close co-operation. Let us see what some of these available resources are.

To begin with, we have scientific research in the health and medical fields, which is a continuous source of new knowledge for the promotion of health and the prevention and cure of disease. The Public Health Service has been conducting such research for more than three decades, and it is safe to say that in so far as occupational diseases are concerned, we now have the knowledge which, if properly applied, would control or prevent all of them. This vast store of information on industrial health hazards has been obtained with the coöperation of industry and labor, in the conduct of our numerous field and laboratory studies.

Next, we have the federal, state, and local industrial hygiene services throughout the nation. Today there are approximately 50 such services functioning in 39 states, in Hawaii, and in the Tennessee Valley Authority. These units employ nearly 400 specialists and expend approximately 1½ million dollars annually. Although most of the state and local units are new—many of them having been created during the past 10 years—they already have made a remarkable record in the prevention and control of industrial disabilities.

Next we have the private practitioners of medicine, acting individually, or collectively through their county and state medical societies. The Council on Industrial Health of the American Medical Association has promoted the organization of committees on industrial health

among the various county and state medical societies. These committees actively develop a better understanding of industrial hygiene problems among all physicians, and especially enlist their interest in giving part-time service to small industries. In several communities, the county medical society committee on industrial health has taken the leadership in coöperative programs—programs with trade associations, labor unions, and other community agencies for the development of health services in local industries. I shall tell you something more about this work later.

In order to obtain many of the general health services in your community, you have, of course, your local health department. There are also the public welfare agencies, and voluntary agencies such as the Red Cross, the social hygiene societies, the local tuberculosis association, and so on. Then, too, there are various types of mutual sick benefit plans, Blue Cross hospital insurance plans, and other methods for the purchase of medical service by workers and their families. There are organizations for recreation and certain community hospital facilities. These and many other agencies, which I need not mention, are at your beck and call and need only to be brought together in an integrated plan to render important services related to health.

I can think of no community better prepared than your own in which to try out such a plan. Coördinated effort is practical, and pays dividends. If the plan has the coöperation of all those involved, it will be sure to have permanency. Such programs are even today functioning in a few of our communities. However, these are the exception rather than the rule. The rule in most of our towns and cities is for each organization to go its own way, often ignoring the wealth of scientific information which is waiting to be

tapped. There are a number of reasons why we permit this gap between our knowledge and its application to our daily lives. One of the reasons has to do with certain deficiencies or needs in health work.

MAJOR DEFICIENCIES IN INDUSTRIAL HEALTH

I should like to mention briefly some of the major health needs which exist to some extent in all parts of the country. To begin with, we have nowhere nearly the number of trained personnel we require for public health work; that is, physicians, engineers, nurses, dentists, chemists, health educators, and other professional workers. Many communities today do not have enough medical man power and facilities to meet current demands; for that matter they never have had enough. The same is true in regard to some of the other professional health workers.

Another major deficiency is in the provision of hospitals and health centers, including facilities for the treatment of such long-term illnesses as tuberculosis and mental disease. Surveys made by the Public Health Service show that the construction of small, well equipped hospitals and health centers to serve rural communities is a particularly urgent need. However, it is especially important that all the hospitals of a state be fitted into one overall plan, in order that the highest type of complete service may be rendered to the people of the area.

There is also a major deficiency in our sanitary facilities, such as public water supplies, sewerage systems, and the like. Estimates show that there are over 10,000 American communities which need to improve their water supplies and sewerage systems, and 5 million rural families in need of better sanitary facilities. There are still many counties, nearly 1,200, without basic public health services, while many of

the remaining 1,800 are operating with greatly depleted staffs.

There is a need for more research not only in industrial hazards but also in diseases of major concern to industrial workers—respiratory infections, heart disease, and cancer—all of which are taking the heaviest tolls in ill health and premature deaths.

We have much to accomplish in connection with industrial health hazards, especially in these days of reconversion. We shall have on our hands the labor force drastically changed by the war. In other words, we have more women in industry, more older workers, and more young workers, to say nothing of veterans with service-connected disabilities and other persons in need of rehabilitation. The problems of conversion in 1940 are with us again in this reconversion period of 1945–1946. Management is doing its utmost to reconvert to consumer production as rapidly as possible. Again, as in 1940, time is precious. Some of the problems already brought about by reconversion are due to the technologic improvements effected in industry by the war itself. For example, the use of light metals, such as aluminum and magnesium, has brought in its wake a serious exposure to fluorides. The growth in the fluorescent lighting industry is associated with exposure to certain compounds and operations which have already caused several deaths and many serious cases of poisoning. The same is true of the greatly expanded plastics industry, which will grow to even greater proportions in the next few years. This is also true of the synthetic rubber industry.

The war gave an opportunity to demonstrate successfully the practical use of industrial x-rays for the detection of flaws in finished products. Some x-ray installations are already using voltages as high as 2 million. It is imperative that these installations be so

designed, operated, and maintained that stray x-rays will not injure workers in the vicinity of the testing machine. The introduction of many new chemicals has resulted in a greater increase in occupational skin diseases and in systemic poisoning.

Perhaps one of the most important problems before us today is that of insuring complete health and medical services to all the people. Much has been said regarding a national medical care program and much more will be said. I am wondering if most people, however, are aware of the need for a broader plan to insure maximum health services. Along with provisions for the purchase of medical care, we must consider the needs for hospitals, diagnostic clinics, and health centers, and must increase the amount and scope of public health services in order to carry out the important task of preventing sickness and unnecessary death. We must make sure that every family in the country has safe water and adequate sanitary facilities. To accomplish these purposes, we must have more trained professional personnel, more scientific research in health and medical fields.

It is not within the province of the present discussion to indicate just how this can be done. Our country has had enough experience in coöperation among federal, state, and local governments, the professions and private agencies, to indicate that the means to provide a comprehensive national health program can be found and will be found. Moreover, the program can be developed in accordance with the needs, resources, and viewpoint of the several states. In fact, a number of states have created commissions to plan for post-war health facilities and services. It should be remembered that the initiative must come from the individual communities and states, themselves.

I have mentioned the problems of small plants. I said that small indus-

tries which are unable to provide the basic services for themselves are more dependent on community health agencies than the larger plants. We should be particularly concerned with their problems, which have been with us always, like the proverbial poor. This brings us to the question of how we should organize for better industrial health in a community.

ORGANIZING FOR INDUSTRIAL HEALTH

The war has taught us that the physical and mental well-being of all our people is our greatest asset. Health is wealth—but wealth is not necessarily health. Industry reaches out into practically every home through its employment of labor, so that the health of industrial employees is also a community problem, requiring well organized community action. This is especially true at the present time when we are on the threshold of a new era—the era of human engineering or “humanics.” We have just passed from the strictly machine engineering age, in which attention was given primarily to the improvement of machinery and processes, to a human engineering era, in which we are concerned with the improvement of the human organism, physically and mentally. This transition is strikingly represented today by the various plans of reconversion, in which consideration is being given to the reconversion of men, as well as machines. An example is the establishment of community rehabilitation for returning veterans.

Now, health is everybody's business; people are “employees” and “employers” only part of the day. The remainder of the time they are plain everyday citizens, just like you and me. Their influence on community action is tremendous and should be used to bring about the provision of community services essential to the maintenance of health. Hence, in any community

planning for health, all groups should be represented. This planning moreover should be for total community health and not for in-plant health services, alone.

Neither I nor any “expert” can give a blueprint of how you should organize for industrial health, nor should I wish to do so even if I had such a blueprint. To be effective and workable, a plan has to be developed by the citizens of the community itself. However, I may be able to leave with you a few guiding principles which have been useful to others in community organization for industrial health.

To begin with, there is a need for a unified approach. An industrial health program needs a grass roots basis. Success can be best accomplished with the help of people and not for them. The second essential is to survey the needs of the community, in other words, to define your problems. Perhaps this may best be accomplished with the aid of your state industrial hygiene service, which has qualified professional personnel to conduct a community-wide study of the various industries in your area, the health hazards of the working environment, and the present facilities within the plants for coping with the various problems revealed.

Defining a problem is only half the battle. You will next need to make an inventory of the various resources which I have described as essential for community action. This can probably be done through a committee of citizens on which will be represented management, labor, your state and local health department, and other community organizations, both official and nonofficial. And, finally, you will want to plan a program to meet the needs, including the means to implement such a program. Let me give you an example of what was accomplished in just one community with regard to industrial health.

In one community, a local trade association, together with the county medical society, launched a campaign for the establishment of an industrial health service which would keep the plants in the area producing at the peak, and maintain the general welfare of the workers on a high level. An industrial health committee was appointed, including on its membership representatives of the various organizations I have just mentioned. As a first step the state industrial hygiene division made an inventory of the physical environment and existing health services of the industries in the community. It was found that most of the plants were small in size and that very few of them had adequate provisions for medical services. In addition, many of them had occupational health hazards in need of correction. Of the 97 plants in this area, only 3 provided cafeteria services for their employees. The survey clearly indicated the need for organized industrial health services in the local industries and provided suggestions for the development of such services. At about the same time, the medical school of the state university offered a post-graduate course in industrial medicine and hygiene for physicians and nurses of the area. The industrial health committee, sponsored by the local chamber of commerce, held a series of meetings to lay the foundation for this coöperative venture. At these meetings members of the health committee presented detailed facts on the costs of the services and other pertinent data. Later a two man team visited the plants to make specific recommendations. Emphasis was placed on what could be accomplished by a good program in those plants which showed high disability rates. Employers were encouraged to introduce the various elements of a sound industrial health program which I have mentioned earlier. Since most of the plants were small, each received

the part-time services of a physician and a nurse, usually paid for on an hourly basis. The amount of time devoted to each plant depended on the population of the plant.

As a result of this program 11 of the larger companies employing approximately 9,000 people now have integrated medical or health units in special departments to give reasonably complete service. Two years ago, only 3 of these plants had such services. Sixty-one of the industries employing about 12,000 workers have some degree of medical service. At least 5 in every 7 plant employees have group health insurance, ranging from partial to complete coverage. The health insurance covers medical, surgical, and hospitalization costs. At least 4 in every 5 employees have had a chest x-ray examination for tuberculosis. The tuberculosis program was extended to include all the children in the area who were over 14 years old. Most of the workers in this community together with their families have been impressed with the real importance of proper nutrition. As a result of the overall program, absenteeism has materially decreased in those plants having health units.

There are other such plans throughout the country which, although not alike in every detail, have certain common denominators. They recognize the tangible benefits to employer and employee through increased production and larger incomes. All have had the support of the local trade association. Today some 250 chambers of commerce have active health committees. These committees are working closely with the local medical societies. All the plans have been developed with the understanding and support of the public. Each one has found the plant survey, as conducted by trained industrial hygienists, an important factor in defining the problems and in pointing

the way for their solution. All of them have included personal contact with management and labor and have emphasized the value of health services for employees of small plants.

SUMMARY

We have demonstrated in our recent war effort that the people of this nation are capable of moving mountains through teamwork and coördinated effort. Furthermore, all of this has been achieved through democratic processes. We have learned that in dealing with the worker we must adopt the concept of "the total man," if we are to bring to him the benefits of modern medicine and hygiene. This, we have seen, requires that we provide for the worker a safe and healthful environment in his place of employment, adequate medical and nursing services in a properly equipped dispensary, such services to include replacement and periodic health examinations, and general health education. The provisions of feeding facilities in the plant and of essential welfare services are also requisites of a good program. Assistance in developing these fundamental services is available in our communities through the many resources which have been developed during the past ten years. What is needed to harness all this potential power is a coördinated pro-

gram in which all of the people, not only employers and employees, will take an active part.

This may seem a gigantic task, but the war has proved that this country can do the impossible. We have the brains, the man power, and the natural resources to do it. We have come out of this war the greatest military and industrial nation in the world. Surely in the peaceful years, we shall use fully our potential strength to create the healthiest nation in the world.

NOTE: For example, in the fiscal year 1945, there were only 3 deaths from TNT poisoning among approximately 100,000 employees engaged in TNT operations. The most hazardous TNT exposures were reduced to safe limits through the use of modern engineering practice. In World War I, the facilities of this country produced 40 per cent of the military explosives used by the Allies; in those plants, there occurred 230 deaths for every billion pounds of explosives manufactured. In the present war, United States facilities produced 95 per cent of all military explosives used by the Allies; only 5 deaths for each billion pounds of explosives occurred. These figures speak eloquently for the application of industrial hygiene.

State Participation in the Evaluation of Local Health Services

L. P. WALTER, M.D., M.P.H.

Director, Local Health Services, Texas State Department of Health, Austin, Tex.

THE Texas State Department of Health has adopted the Evaluation Program of the American Public Health Association as a device for improving the quality and quantity of public health work throughout the entire state. Promotion of the *Evaluation Schedule* on a state-wide basis was undertaken only after its value had been definitely proved in a few communities.

Throughout the years, some Texas communities had periodically prepared *Evaluation Schedules* and submitted them for grading during the regime of the Health Conservation Contest and the National Health Honor Roll. Three years ago, when the Association changed the emphasis of the Program by encouraging participation of local units only with and through state health departments, 8 Texas communities submitted schedules and were included in *Health Practice Indices 1941-1942*, 18 communities were reported in the 1943 issue, and 34 in the 1943-1944 edition.

The extent to which a state should participate in the evaluation of local health services may depend on the degree of responsibility for administration of the program in the local areas. There is wide variation in public health administration throughout the United States. In some areas, local officials assume most of the responsibility for financing and operating the full-time health services; in other areas, the state department of health assumes most of the responsibility for their operation.

Between these two extremes there are many differences.

In Texas, the State Department of Health has assumed the leadership in the promotion of full-time local health services. The territory of the State of Texas covers about one-eleventh of the United States, and this vast area is divided into 254 counties, 60 of which are served by full-time local health service. A wide experience over a long period of time proved that unless the State Department of Health stimulated some of the local communities to the realization of the need for better public health service, practically no progress would be made. Responsibility for administration of the public health program in most Texas communities is divided between the local appropriating agencies and the State Department of Health. Since the funds appropriated by the Texas Legislature are inadequate for expansion of the program, much needed grants-in-aid are accepted from the federal government. These funds are allocated to local communities in accordance with the rules and regulations formulated by the federal government.

The 60 counties in Texas receiving full-time local health services are covered by 47 health units. In each of these health units, at the present time, at least 50 per cent of the funds for operating expenses must come from the local appropriating agencies. In many units the ratio of local funds is much

greater than 50 per cent. However, no health unit receives over \$50,000 per year from the State Department of Health. It is, therefore, not only the responsibility of the local appropriating agencies, but also the responsibility of the Texas State Department to evaluate periodically the public health services that are rendered.

When a modern health unit is established with full-time qualified personnel, financed largely from local funds, there is usually more local interest in the efficiency and economy of its operation. Even in such areas, where the public health program is primarily the responsibility of the local communities, the state health department can at times render valuable consultative assistance in program planning and in meeting emergencies. In order to render a service which will be respected by the local communities, a state department of health should have proper equipment and be manned by highly trained personnel.

It is impossible to render adequate services unless the state department of health is informed at all times relative to the public health needs through the state. These needs cannot be known accurately except by means of a periodic evaluation. An occasional visit to a community will not produce the needed information. Random reports received from interested citizens may conflict. Complaints sent to the state department by local officials may be biased because of political influence. Newspaper reports concerning local public health affairs are frequently inaccurate. When facts concerning local public health conditions are obtained in an irregular haphazard manner there is no basis for comparing the health program of one county with that of another. A comparison which is statistically sound is desirable when recommendations are made for allocation of funds, placement of specialized

personnel, and in many other activities from the state level. An annual evaluation will show the need for economy in the use of all funds appropriated for public health. There may be four or five governmental jurisdictions within a county asking for state financial assistance in setting up a full-time health service. If *Evaluation Schedules* are prepared, duplication of services is made obvious.

The American Public Health Association, in coöperation with the Texas State Department of Health, has prepared "blue-prints" for a minimum public health program in Texas.* This program calls for establishment of 80 health units. These units, in many instances, are made up of several counties and, unless the State Department of Health has some tangible documentary evidence to show the need for multi-county units, difficulty may be experienced in answering the questions which arise in the organization of such units.

By studying the *Evaluation Schedules* and *Health Practice Indices*, the State Department is able to view the public health picture as a whole. The *Indices* serve as a guide for demonstrating to newly recruited health officers the needs and activities of particular areas, and are an aid in fitting the physician's special aptitudes to community needs.

The first *Evaluation Schedules* which were prepared by most communities in Texas were not completely executed because the health unit and other agencies did not have their records established in such a manner that the information could be obtained. Marked improvement was shown in succeeding schedules, which may be attributed in part to the inauguration of a standardized record system through the state, and to assistance given the local units by two technical field clerks who have

* Emerson, Haven. *Local Health Units for the Nation*. New York: Commonwealth Fund, 1945.

been given special training in the preparation of the *Evaluation Schedule*. Many requests are made by the local communities for the services of the technical field clerks, and by careful arrangement of itineraries the department is able to supply this assistance.

In Texas the preparation of the *Evaluation Schedule* is placed entirely on a voluntary basis, and there has been enthusiastic response. The *Schedules* vividly show where there is a conflict between the official and non-official agencies. Frequently the *Schedule* is a means of eliminating many unnecessary attempts to carry on programs which should be under the official health department.

It is true that some health officers when they see the *Evaluation Schedule* for the first time state that it is too long, takes too much work, and is "a foolish idea." Others immediately see the value of the device and grasp the opportunity to use it in the improvement of their programs. After the health officers have assisted their communities in filling out the *Schedule* for several years, they all agree that the time and energy expended have been worth while. Health unit directors recently returned from military service find the *Evaluation Schedules* and *Health Practice Indices* excellent sources of information as to what has transpired during their absence. In planning their future programs, the *Evaluation Schedules* should show the greatest needs in their communities.

Through the use of the *Schedule*, the local health officer can readily determine whether or not the community is making progress in recognized public health activities by making annual comparisons. The facts can be presented to the local appropriating agencies, and frequently additional appropriations for the advancement of the program can be secured.

As a means of community health

education, the *Evaluation Schedule* and *Health Practice Indices* can be utilized in many respects. For example, the health officer can use these publications in joint meetings with other agencies, such as welfare, hospital, and public works groups. The Texas State Department of Health has been actively engaged in using the *Indices* in a state-wide health education program.

For in-service training purposes the State Department of Health has prepared lantern slides of the charts in *Health Practice Indices*. Periodically, the State Department sponsors a general meeting of health unit directors, and by means of lantern slide demonstrations, the health officers can readily visualize which communities are making the most progress in solving urgent public health problems. Where two or more health officers have similar problems, they can hold conferences which are mutually beneficial.

The American Public Health Association has coöperated in every respect with the Texas State Department of Health in the preparation of the *Schedules*. In our opinion the evaluation should be carried on through the State Department of Health in order to avoid duplication and conflicts, and the personnel at the state level should be trained in the methods suggested by the American Public Health Association in order to visualize the entire scope of the program.

Following an invitation from the Association last year, the State Health Officer of Texas sent a group of representatives to an Institute on the Evaluation of Public Health Practices conducted by the School of Public Health at the University of Michigan in Ann Arbor. At this Institute representatives from ten states were given opportunity for the study of *Evaluation Schedules* and were trained in grading the reports.

Evaluation Schedules in Texas are

handled in the following manner: Four blank schedules are sent to each community; one is used as a work sheet, one completed copy is filed in the local health unit, one is sent directly to the American Public Health Association, and one to the Texas State Department of Health. Last year, the *Schedules* were graded by both the American Public Health Association and the Texas State Department of Health. The same standards were used in the

grading and there was remarkable similarity in the final results.

The American Public Health Association has announced that it will continue to render this service to the various states.

It is hoped that the local communities and the state departments of health will continue to utilize to the fullest extent these tools for improvement in the quality and quantity of public health work.

Coördination of Voluntary Health Agencies Is a Live Issue

Voluntary Health Agencies: An Interpretive Study, familiarly known as the Gunn-Platt Report, is starting a wave of "town meetings" throughout the country. Although it has been off the press only six months, many health organizations have held forums of executive members to discuss its implications and recommendations — the Onondaga Health Association and the Hartford Visiting Nurse's Association to mention only two examples.

Other agencies have scheduled board member meetings to discuss the study and to ponder its "recommendations to revitalize local voluntary health agencies by means of effecting coördinated health planning and simplifying and unifying appeals for public support," among others. In these discussion meetings,

board members are testing their readiness to "adapt their efforts to the changing realities," and "to abandon forms and cling firmly to realities." The Boston Health League and Pennsylvania Planned Parenthood Federation are among agencies that have had this type of soul searching.

But the study has had discussion in other circles as well. The *Survey Monthly* devoted its entire issue of October 15 to a discussion of the various aspects of the report in seven articles by public health leaders. The *American Journal of Public Health* and *New York Medicine* have discussed it, as well as such varied national magazines as *The Nation*, the *New Republic* and *McCalls*. It has also had a wide discussion in newspapers.

Observations Concerning the Growth of Three Species of *Shigella* on Bismuth Sulfite Agar

MILDRED M. GALTON AND NANCY J. COLLINS

Bacteriologists, Bureau of Laboratories, State Board of Health, Jacksonville, Fla.

A REVIEW of the literature has failed to reveal any reports recommending bismuth sulfite agar for the isolation of the members of the *Shigella* group. It is generally recognized that no significant growth of these organisms occurs on this medium.¹ The *Difco Manual*, 1943, states that generally members of the dysentery group are inhibited, although some strains of Flexner and Sonne do develop. Some investigators indicate that they are completely inhibited. Sellers² regards this as one of the disadvantages of bismuth sulfite agar. In view of these facts it seems feasible to report our observations.

For the past 3 years bismuth sulfite agar, Difco (W. B.) and S. S. agar have been used for direct plating of all feces cultures in the Florida State Board of Health Laboratories. During the first 2½ years we found an occasional culture of *Shigella alkalescens* on W. B. agar, but the number was so small it seemed of no significance. In December, 1944, a definite increase in the number of alkalescens isolations was noticed, the majority of which were found on W. B. agar, while the S. S. plates were negative. At this time pure cultures were plated on W. B. agar and the colonies closely observed. We found that they were quite varied in appearance, ranging from very pale green to a dark, brownish green, smooth and glistening.

Some are raised, ameboid in shape, and mucoid in appearance, while others are flat and round. Colonies with dark green center and lighter green periphery are also formed. The predominating type found almost consistently from directly plated feces cultures is a medium green colony, smooth, glistening, slightly raised, and frequently ameboid in shape.

TABLE 1

Results of 136 Shigella alkalescens Isolations

<i>S. alkalescens</i>	<i>S. S. W. B.</i>	
<i>Positive</i>	65	108
" on W. B. only		71
" " S. S. "	28	
" " " and W. B.	37	37

We continued to pick colonies of the types described above and in July, 1945, isolated 5 cultures of *Shigella paradysenteriae*, Boyd 88.* Of these, 3 were negative on S. S. agar. The colonies were very similar to those of *S. alkalescens*; however, in pure culture they were not as varied in color and form, the light green with slightly darker green center, flat and glistening type being predominant. One culture produced brownish green raised colonies with crater-like centers. Other Boyd 88 cultures in our collection produced luxuriant growth when plated from a pure culture on W. B. agar.

* Identification confirmed by Dr. K. M. Wheeler, Connecticut State Health Department Laboratories, Hartford, Conn.

The third species of *Shigella* that we have found on bismuth sulfite agar is *Shigella dispar*. Colonies of this type also resemble those of *S. alkalescens*. The identity of 2 of these cultures has been confirmed.*

While *S. alkalescens* is frequently found in normal persons, more recent reports indicate that it can also cause sporadic cases or epidemics of dysentery and gastroenteritis.³⁻⁵ Therefore, since W. B. agar is so widely used in direct plating of stool cultures, it seems

notable that a member of the *Shigella* group apparently grows better on this medium than on S. S. agar. The fact that 2 other species of *Shigella* have been isolated on W. B. agar warrants further observation.

Good Health in 1945

The December, 1945, *Statistical Bulletin* of the Metropolitan Life Insurance Company might very well have been entitled "Count your blessings—one by one." It reports, for example, that the maternal death rate in New York City has declined 73 per cent since 1933 and about one-third since 1939 in the United States; that infant mortality in the United States declined to a record low during the war with the greatest relative improvement in the West South Central and Mountain States where the rates are highest; that death rates have continued to decline and the natural increase in population

to rise; that the number of marriages, which temporarily declined in 1944, rose again in 1945, with the Mountain and Pacific States having had from a 50 to 85 per cent increase each of the four years beginning with 1942.

The sour note in the statistical picture is a slight increase in fatal accidents due to the increase in motor vehicle accidents following V-J Day and a slight increase in home accidents (Watch that loose rug!). Occupational fatalities were kept at pre-war levels throughout the war and catastrophic accidents were fewer in 1945 than in 1944.

PLANNING FOR PARENTHOOD

OUR leading Review Article in this issue of the JOURNAL deals with a topic of great and increasing moment in the field of public health. Phenomenal advances in the reduction of maternal and infant mortality during the past quarter-century have been due chiefly to control of environmental factors, improvement in milk supply and in the general nutrition of mother and infant, and protection against microbic infection. We discussed in our February issue possibilities of further improvements as a result of recent progress in our understanding of blood chemistry as associated with the puerperal state. The health worker today is face-to-face with a residual of maternal and infant deaths related to more basic physiological factors. We are forced to the conclusion that future advance must depend not merely on how the baby shall be borne and cared for—but also on whether it should be conceived at all by a given woman at a given time. The logical progress of true preventive thinking leads us inevitably to the consideration of fertility control.

The decision whether childbearing is a relatively safe and wise adventure depends on many factors. At the Spartanburg County Maternal Health Clinic, 40 per cent of the patients are referred because of serious specific illnesses such as tuberculosis, syphilis, heart disease, nephritis, or pellagra; 30 per cent because of anemia or general debility; and 10 per cent for other medical reasons. Low economic status, alone, however, may be a sound contraindication for pregnancy, since our principle must be that no child should be born into a family where it cannot be provided with the essential conditions of healthful living without a strain upon other members of the family which will, in turn, menace their health. In a wider sense, the restraint of population increase within reasonable limits may be a primary requisite for the promotion of general community health in certain areas (as in Puerto Rico or India).

Dr. Stix's review cites ample and striking evidence of the practical effectiveness of the contraceptive procedures now available, a point which has been raised by certain captious critics. Even crude methods applied without special instruction may reduce pregnancy rates by 25–50 per cent. a result by no means

negligible; more reliable methods, applied under advice, reduce pregnancies by 80-95 per cent. Flexibility of procedures and their application to the psychology of individual couples should be strongly emphasized. For the careful studies which have provided our knowledge in this field we owe a very real debt to the late Raymond Pearl and to the investigators supported by the Milbank Memorial Fund, whose recent contributions have been of far-reaching significance.

Birth control is something that should work both ways. We do not "control" an automobile solely by applying the brake. No inconsiderable proportion of non-fertile families desire to have children, as evidenced by the number of adoptions in economically self-sufficient groups. This problem is a difficult one and requires association with well equipped and staffed general hospitals; but it should not be omitted from any comprehensive community program for planned parenthood.

Outstanding advances have been made in the general field of preventive birth control programs in such southern states as the Carolinas, Alabama, Florida, Mississippi, and Texas. The U. S. Public Health Service in 1941 indicated its readiness to assist a child spacing program undertaken by any state (where local laws do not interfere) on the same basis as any other part of its public health program. So far as the medical profession is concerned, Dr. Stix rightly says "For the women to whom pregnancy would constitute a serious health hazard, there is no choice for the physician but to offer the most effective contraceptive methods available, to perform a sterilization operation, or to counsel abstinence for long periods." The second of these alternatives is justified only in certain special cases, and the third is fraught with serious hazards from the standpoint of mental hygiene. The first is, in general, the method of choice. The way for advance is open along an important road toward higher levels of public health. Only in the states of Connecticut and Massachusetts does the iron hand of theocracy bar the road.

THE NATION'S HEALTH

ON October 4, 1944, the Governing Council of the American Public Health Association adopted an official statement outlining a national program for the protection of the health of the people of the United States.¹ On November 19, 1945, President Truman sent a special message to the Congress on the same subject; and the general principles embodied in the President's message were embodied in a bill (S. 1606 and H.R. 4730) introduced by Senators Wagner and Murray and Representative Dingell, and in a bill introduced by Senators Hill and Burton (S. 191) and by Representatives Neely and Patrick (H.R. 2498, 2755). It would seem of interest, at this time, to compare these four documents and to see how far they coincide and wherein they differ.

The Problem—The problem to be solved was outlined in our A.P.H.A. statement as follows: "A large portion of the population receives insufficient and inadequate medical care, chiefly because persons are unable to pay the costs of services on an individual payment basis when they are needed, or because the services are not available." Special deficiencies were noted in regard to physical facilities, such as hospitals, health centers, and laboratories; number and distribution of personnel; number of qualified administrators; provision of organized local public health services; and adequate scope of scientific research.

President Truman says: "In the past, the benefits of modern medical science have not been enjoyed by our citizens with any degree of equality. Nor are they today. Nor will they be in the future unless government is bold enough to do something about it. People with low or moderate incomes do not get the same medical attention as those with high incomes. The poor have more sickness, but they get less medical care. People who live in rural areas do not get the same amount or quality of medical attention as those who live in our cities." He calls special attention to inequality in distribution of doctors and hospitals, to the need for development of public health services and maternal and child care, to the need for furthering research and professional education in the health field, to the importance of developing resources to meet the high and variable costs of medical care and to the problem of compensation for loss of earnings due to sickness.

General Objectives—The A.P.H.A. resolutions state that: "1. A national program for medical care should make available to the entire population all essential preventive, diagnostic, and curative services; 2. Such a program should insure that the services provided be of the highest standard, and that they be rendered under conditions satisfactory both to the public and to the professions; 3. Such a program should include the constant evaluation of practices and the extension of scientific knowledge."

The President's message says that "Our new economic bill of rights should mean health security for all, regardless of residence, station, or race—everywhere in the United States." Provisions for maintaining standards of quality, methods of establishing conditions satisfactory both to the public and to the professions and research will be discussed in succeeding paragraphs.

Scope of Services—The American Public Health Association statement suggests that, ultimately ("within ten years"), service should be comprehensive, including hospital care, services of general practitioners, and specialists, laboratory and diagnostic services, nursing care, essential dental services, and prescribed medicine and appliances. "At the outset, as many of the services as possible should be provided for the nation as a whole, having regard for resources in personnel and facilities in local areas. The scope of service should then be extended as rapidly as possible."

President Truman says that "a system of prepayment should cover medical, hospital, nursing and laboratory services. It should also cover dental care—as fully and for as many of the population as the available professional personnel and the financial resources of the system permit." The Wagner-Murray-Dingell Bill contemplates comprehensive personal health services, except for possible temporary limitations in the fields of nursing and dental care, and limitations on the period of hospitalization.

Our report considers it "imperative that the plan include and emphasize the provision of preventive services for the whole population." It calls for increased federal and state grants to extend public health services to all areas; and for study of methods to attain better coordination of health activities. President Truman states that "No area in the Nation should continue to be without the services of a full-time health officer and other essential personnel. No area should be without essential public health services or sanitation facilities. No area should be without community health services, such as maternal and child health care." The first title of the Wagner-Murray-Dingell Bill provides for far-reaching stimulation of such services by grants to states through the U. S. Public Health Service and the Children's Bureau.

The American Public Health Association statement says: "In so far as may be consistent with the requirements of a national plan, states and communities should have wide latitude in adapting their services and methods of administration to local needs and conditions." The President says: "Medical services are personal. Therefore, the Nation-wide system must be highly decentralized in administration. The local administrative unit must be the keystone of the system so as to provide for local services and adaptation to local needs and conditions."

Financial Support—Our 1944 resolutions state that "services should be adequately and securely financed through social insurance supplemented by general taxation or by general taxation alone" (since social insurance alone would exclude certain economic groups). The President recommends that the public health and the maternal and child health services be made more effective "by more generous grants to the states than are provided under present laws" (tax supported); and he recommends that the basic problem of personal medical care be solved "by distributing the costs through expansion of our existing compulsory social insurance system. . . . How much of the total fund should come from the insurance premiums and how much from general revenues is a matter for the Congress to decide." The contribution from taxation is provided for in the Wagner Bill, Title I, which deals with direct financial coöperation with the states in supporting public health services (Part A), maternal and child services (Part B), and payment for the personal medical care of needy persons (Part C). Prepaid personal health services for employed persons and their dependents are provided under a system of compulsory insurance in Title II, with the source of funds not specified, but indicated to be a combination of insurance premiums and general revenues. Federal grants for hospital surveys and construction under the Hill-Burton Bill would come from general revenues.

Our report calls for "services financed on a nation-wide basis in accordance with ability to pay, with federal and state participation, and under conditions which will permit the federal government to equalize the burden of cost among the states." This, is, of course, provided for under the Wagner-Murray-Dingell and Hill-Burton Bills. Grants to the states are adjusted to per capita income; even insurance premiums are substantially on an ability-to-pay basis. The President points out that the insurance "health fund should be built up nationally in order to establish the broadest and most stable basis for spreading the costs of illness, and to assure adequate financial support for doctors and hospitals everywhere. If we were to rely on state-by-state action only, many years would elapse before we had any general coverage."

Administration—The American Public Health Association program makes four specific recommendations in this field.

First, it calls for a single responsible administrative agency at each level—federal, state, and local, and adds that "the public health agencies should carry major responsibilities in administering the health services of the future." The Wagner-Murray-Dingell Bill places administrative responsibility at the federal level for prepaid medical care and all other phases of the program—except grants for maternal and child care and grants for the medical care of needy persons—under the Surgeon General of the U. S. Public Health Service. The system of grants-in-aid to state welfare agencies for the care of needy persons to be administered by the Social Security Board involves a primarily fiscal operation at the

national level. Both the Surgeon General and the Board are under the Federal Security Administrator. The latter provision is obviously essential, since plans cannot be made for spending funds unless the funds are available. Under the Hill-Burton Bill, the Surgeon General would administer the program at the federal level. Therefore the only deviation from the principles of our resolution lies in the continuance of the Children's Bureau as an independent federal operating agency. On the state and local levels the U. S. Public Health Service will, of course, continue to work through state and local health departments in its grants for public health services. It would have wide latitude in negotiating with state and local agencies for the prepaid personal service to employed persons and their dependents. The way is clear for utilization of state and local health departments, in so far as they are ready and competent to undertake such responsibilities. If the health functions of the Children's Bureau should be transferred to a new Department of Health and Welfare—as has been proposed—all parts of the program would be under one tent.

The second of our principles is that the administering agency should have the advice and counsel of a body representing the professions, other sources of services and the recipients of services. This aim is visualized by the President in his statement that "Locally as well as nationally, policy and administration should be guided by advisory committees in which the public and the medical professions are represented." It is spelled out in detail in the Wagner-Murray-Dingell Bill which provides for a National Advisory Medical Policy Council representing the professions and the public, to be appointed by the Surgeon General from panels of names submitted by the professional and other groups concerned and from the public. This Council shall establish special advisory technical regional or local committees or commissions. Its primary duty is to provide for "professional standards of quality to apply to personal health service benefits."

The third point made in our 1944 resolutions is that private practitioners in each local area should be paid according to the method they prefer—fee-for-service, capitation, salary, or any combination of these three. This is precisely the procedure embodied in the Wagner-Murray-Dingell Bill, the general method of payment in each local area to be determined by vote of the general medical and family practitioners (or general dental practitioners) in that area; and there is provision for other methods of payment to be used, as they may prefer, by minorities.

Finally, the American Public Health Association resolutions state that the principle of free choice should be preserved to the population and the profession. President Truman says: "People should remain free to choose their own physicians and hospitals. The removal of financial barriers between patient and doctor would enlarge the present freedom of choice." "Likewise, physicians should remain free to accept or reject patients. They must be allowed to decide for themselves whether they wish to participate in the health-insurance system, full-time, part-time, or not at all." "Our voluntary hospitals and our city, county, and state general hospitals, in the same way, must be free to participate in the system to whatever extent they wish." "Voluntary organizations which provide health services that meet reasonable standards of quality should be entitled to furnish services under the insurance system and to be reimbursed for them." The provisions of the Wagner-Murray-Dingell Bill are in full accord with these policies.

With these provisions in mind, we may return to the statement made by the

American Public Health Association in 1944 that national health services should be rendered "under conditions satisfactory both to the public and to the professions." The way in which the public chooses to accumulate funds to pay for medical service is a matter for the determination of the public, whose money is involved. The way in which that money is spent is, however, of obvious importance to the professions upon whose efforts the quality of service depends. The main issues here are centralization of administration in expert hands, provision for the expression of professional opinion in regard to policy, a method of payment for services rendered by practitioners and agencies satisfactory to them, and freedom of choice for all concerned. The safeguards on these four points outlined by the American Public Health Association are all included in pending legislation.

Provision of Physical Facilities—With respect to construction of hospitals, health centers, and laboratories, our report of 1944 advocated construction based on federal aid to the states and allowance for participation by voluntary as well as public agencies (with suitable controls). It advocated grants on a variable matching basis. It held that the U. S. Public Health Service should administer the program on the federal level and that grants should be in accord with the results of state surveys and master plans, or, in the absence of state plans, should follow a U. S. Public Health Service survey. Construction should be undertaken only where there was reasonable assurance of continued support and maintenance.

The recommendation of grants for developing such physical facilities, and precisely under these terms, is included in President Truman's message; and also in the Hill-Burton Bill, though there are differences of opinion whether all of the safeguards and controls are contained in this Bill. Amendments on these points will be under discussion when the House Committee considers the Bill passed by the Senate.

Training and Distribution of Personnel—The 1944 resolutions called for further federal assistance in the training of professional and auxiliary personnel and, particularly, of administrators; and for the application of financial stimulus to encourage service in rural areas. This point was emphasized in the President's message and is fully implemented in Titles I and II of the Wagner-Murray-Dingell Bill.

Research—Our resolutions called for increased funds to be used by the Public Health Service, by state and local health departments and other nonprofit institutions for research and demonstration; and suggested that grants for such research be made with the "assistance of competent professional advisory bodies." The President strongly recommends the support of research. The Wagner-Murray-Dingell Bill includes research and the performance of demonstrations as suitable subjects for federal aid under both Titles I and II. All such grants would be made in consultation with advisory councils.

In summary, it may be said that the President's message and the two principal Bills which embody it in concrete legislative form appear to be in complete accord with the program adopted by the American Public Health Association as to needs and major objectives; and in almost complete agreement with that program as to details of policy and procedure.

THE TREATMENT OF INDUSTRIAL WASTES

A RECENT issue of *Sewage Works Engineering*¹ was devoted to a problem which deserves the serious attention of public health engineers and also of health administrators, since basic questions of general policy are involved.

J. K. Hoskins of the U. S. Public Health Service estimates that the inland waterways of the United States receive a volume of waste from domestic sewage equivalent to the raw sewage of 47 million persons; while these same waterways receive industrial wastes equivalent to the raw sewage of 55-60 million persons. According to M. M. Cohn, "These industrial wastes are as complex as the manufacturing processes and products that come from the industries which produce a great parade of goods and commodities—food, textiles, paper, leather, steel, alloys and other metals, chemicals, rubber and hundreds of other items of a vast nation. They represent the tailings of the materials produced, such as cannery, food wastes, paper-pulp wastes, dairy wastes; dirt and process wastings, such as wool scourings; oils and greases from such industries as slaughterhouses and machine shops; soap wastes from laundries; chemicals and dyes; acids from steel mills and coal mine drainage; and like materials too numerous to mention."

In many instances, proper treatment of industrial sewage makes possible the recovery of waste products whose value would far more than pay for the cost of treatment. F. W. Mohlman lists a large number of instances in which installation of adequate machinery would lead to profitable recovery of waste products and pay-off of the equipment cost in a few years. One plant loses 12 tons of acetic acid per day, which if recovered would pay for the cost of equipment (one million dollars) in about two years. Another loses 5-10 tons of grease per day, in these times of grease shortages. Another loses starch and gluten; another hundreds of barrels of oil per month; another a half-ton or so of copper per day. A considerable number of individual plants and a few trade associations are cited which have attacked such problems as these with intelligence and vigor. A. M. Rawn and H. W. Gehm cite examples of highly profitable recovery of sulfite wool wastes and pulp and paper mill wastes.

Obviously, by no means all industrial wastes can be treated in such a way as to yield financial gain. But—profitable or not—treatment of such wastes before discharge into public sewers or streams must be required in the public interest. Some untreated industrial wastes may work serious damage to the sewerage system itself through corrosive action; and nearly all of them, as D. E. Bloodgood tells us, interfere with the operation of sewage disposal plants. Where they are discharged into public sewerage systems, W. T. Knowlton points out, each industrial plant should be required to pay its share of the excess burden placed upon the disposal plant, on a basis of the additional load of biological oxygen demand and suspended solids involved. English experience shows that a reasonable basis for such charges can be readily worked out. Where the industrial wastes are discharged directly into a stream, public health and waterways authorities should require such preliminary treatment as will avoid menaces to health, creation of nuisances, or damage to aquatic life, and will protect recreational facilities.

The cost of such treatment is a fair and reasonable part of the cost of production. "The cost of wastes treatment is as much a cost of manufacturing as is the cost of the crude material and labor that go into the product." R. D.

Hook, however, calls attention to the fact that "Until there is reasonable uniformity in the requirements of the several states, such a solution to the problem is unlikely to be adopted because of competitive disadvantage." The U. S. Public Health Service might profitably undertake a systematic effort to secure such reasonable uniformity through cooperative state action.

WALLER SMITH LEATHERS

OUR Association has lost another of its distinguished leaders in the death on January 26 of Waller Leathers.

Dr. Leathers was born in Virginia in 1874. He was trained at the University of Virginia and took his medical degree there in 1895. Like Sedgwick, he began his career as a teacher of chemistry, biology, and physiology. He was on the faculty of various southern universities between 1896 and 1899; and joined the faculty of the University of Mississippi in 1899. Here, he served for a quarter of a century, as Professor of Physiology and Hygiene and organizer and Dean of the School of Medicine. During this period he was Director of Public Health for the State in 1910, and again from 1917 to 1924. Between 1924 and 1945 he was on the faculty of Vanderbilt University as Professor of Preventive Medicine and Public Health and as Dean of the Medical School (from 1928). He held many voluntary posts of far-reaching influence, as adviser to the Rockefeller Foundation, the Commonwealth Fund, the American Red Cross, and the United States Public Health Service.

Dr. Leathers was a nationally outstanding figure in medical education, serving as a member of the National Board of Medical Examiners for many years and as its President from 1930 to 1934 and from 1936 to 1942. He was active in the American Public Health Association, organizing and for many years directing the work of the Committee on Professional Education, and was President of the Association for 1940-1941. He was also a leader in the American Medical Association, holding the posts of Secretary (1920-1923) and Chairman (1923-1924) of its Section on Preventive and Industrial Medicine and Public Health. His connection with these two organizations was of material value in promoting good understanding and cooperation between them in the common cause of public health.

Waller Leathers was an ideal executive and a devoted public servant. He was conscientious and thorough in all that he undertook. His balanced judgment, his fairness and his reasonableness, inspired the confidence which made his wide and constructive influence possible.

LETTER TO THE EDITOR

TO THE EDITOR:

Because of your editorial entitled "The Test of King Solomon," which appeared in the November issue of the *American Journal of Public Health*, I thought you might be interested in the coöperative activities of the Washington Department of Public Instruction and the Washington Department of Public Health. I am, therefore, briefly summarizing our efforts to date.

Beginning in 1942 there was a concerted effort for the two state departments to work together toward a more coöperative and unified program. This start resulted from the meeting of the health officers' Records and Forms Committee with a committee from the State Department of Public Instruction to revise and plan for the Pupil Health Card and the Pupil Medical Record. The interpretation for the use of each of the cards was also published in booklet form. This brought to realization of both state departments and their local components that coöperation was fruitful and desirable.

In 1944 the State Department of Public Instruction undertook a demonstration project in conjunction with the State Department of Health and funds were obtained from the Kellogg Foundation for improving the overall school health program. In this coöperative effort, the State Department of Health made available to the State Department of Public Instruction a health educator to work full time in this coöperative program. This project resulted in workshops throughout the state for educators and for local health department personnel. It also resulted in the publication by the State Health Department of a *Guide to School Health Services*, which many of the

local health departments and school directors are now following.

The *Guide* undertakes to improve the school health program through the development of four broad phases:

1. To revise the curriculum so as to bring it up to date as far as scientific health information is concerned and to see that all students receive instruction in health matters, as well as to eliminate repetition.

2. To improve school health services, including nursing services, physicians' services, sanitarians' services, as well as other health department services which may be available.

3. To provide integration by interesting the local school administrator in the appointment of a health council or committee so that opportunities for teaching experience offered in health programs in the community may be utilized in the school curriculum and by providing an opportunity for students to observe as well as participate in these health programs of the community.

4. To interest the school administrator in designating or employing a school health coordinator whose responsibility would be to see that the three policies outlined above are carried out completely.

The major concern at present is to get the local health officer and his staff to meet with the school administrator and a good representation from the school staff to discuss and plan the local school health program. If these meetings can occur at least twice a year and if the policies laid down in the *Guide* are followed, adequate school health programs will eventually result.

In 1945 the Departments of Public Instruction and of Public Health appointed a Joint Committee on School Health. This joint committee discusses school health problems and lays plans for solving these problems. It also sees to it that this information is carried to their respective local organizations. A committee from the Depart-

ment of Public Health is currently working with a committee from the Department of Public Instruction in revising the latter's health and physical education curriculum.

I am happy to be able to say that the state departments, as well as the local

health departments and local school directors, are working more closely together than ever before in the State's history.

ARTHUR L. RINGLE, M.D.

*State Director of Health
Seattle, Wash.*

TO THE EDITOR:

Through the medium of the American Journal of Public Health, I want to extend congratulations to Doctor Raymond S. Patterson on his section, "Selected Public Health Bibliography with annotations," emphasis on the

"annotations." His light touch certainly traps the reader into running through the whole section.

HELEN R. ODELL

11 South Lake Avenue
Albany 3, N. Y.

Dr. Sawyer of UNRRA Reports on Poland

Dr. W. A. Sawyer, UNRRA's Director of Health, completed a two month tour of Poland early in January. He consulted both with Poland's public health officials and the UNRRA staff, visited hospitals, health centers, and medical schools, and lectured on the discoveries and new methods in public health and medicine in five cities to doctors isolated from outside advances in medicine for six years.

One sentence epitomizes his report, "The spirit of Poland is as wonderful as the conditions are appalling." - Without food, shelter, clothing, without transport, without medical supplies, only courage and will are left.

Competent health officials both in the central Ministry of Health and in the field are using the facilities provided by UNRRA to cope with the difficulties. UNRRA is bringing in by truck bedsteads, mattresses, and blankets and sheets for hospitals; it is providing ambulances and trucks, many tons of DDT powder, supplies of diphtheria antitoxin, as well as professional health consultants.

A few sentences from Dr. Sawyer's report serve to paint the picture.

"I saw contagious disease sufferers lying on straw ticks and covered with blankets, threadbare and full of holes, which they had brought with them. No others were available. Such sheets as there are in the country are worn and patched. Adults get practically no milk. A standard meal in one hospital was small potatoes in their skins with a cereal gruel, with meat or an egg only once in a week or two. The work of doctors, whose numbers were heavily reduced by the war, is hampered by lack of transportation. I saw a patient being conveyed to a hospital in a horse-drawn farm cart. Lying on straw he was travelling the many miles to the nearest hospital in zero weather. Typhus is present in widely distributed areas, but not a serious epidemic yet. The most serious problem is that of preventing the spread of typhoid fever, a problem aggravated by the tremendous movements of population. In September there were 16,600 notified cases of typhoid. Poland is almost totally devoid of diphtheria toxoid. Tuberculosis is widespread."

These are the conditions which make Dr. Sawyer say, "The picture presented by Poland today is that of a country recovering from a degree of physical destruction and personal suffering hard to imagine and impossible to describe."

Credit Lines

SEEING IS BELIEVING

Credit Lines is indebted to Dr. Raymond S. Patterson for this item

This may be old-hat to people who gad about the country, but it is pure new-bonnet to one who is glued to his desk. It seems that the extension people at the University of Virginia induced a foundation to subsidize a traveling clinic through which a handful of community leaders were enabled to go out to visit a dozen interesting community ventures in public health and welfare. The "students" talked over their three-state Odyssey when they returned home from their wanderings and some of their conversation is recorded in "We Went to See for Ourselves . . .," the January 1, 1945, issue of the University of Virginia Extension.

Among the community enterprises they saw at firsthand were community recreation projects, schools, libraries, farmers' coöperatives, combined health districts. Then at the end of their trip they sat on the veranda and gossiped about health education with Lucy Morgan and a brace of her disciples. If you read the testimony, little doubt will remain in your mind but that here is a potent mechanism for stimulating better community health services in many sections of our country.

There is no hint of limit of the supply of this unusual publication or of the good nature of the publishers, so it is suggested that you write pronto to the Extension Division of the University of Charlottesville, Virginia, and ask for a copy of Vol. 22, No. 8, which is the identifying number of "We Went to See." While you are imposing on the generosity of the Division, ask for those issues of "*New Dominion Series*" which describe the community health

projects the peripatetic scrutinizers visited, and for good measure ask for No. 71 of that series, entitled "The Community and Health. Health Educators Make Planning a Two-Way Process."

HEALTH EDUCATION AND DENTAL HEALTH IN KANSAS

Credit Lines has just received two volumes, *Health Education in Elementary and Secondary Schools*, and *Health Education in Colleges*, outlining a coöperative health education program being carried on by the Kansas State Board of Health and the State Department of Education. The material has been prepared by the Policy-Making Committee on Health Education of the Kansas State Health Education Council, under the direction of Dr. F. C. Beelman, State Health Officer. Professor Clair E. Turner served as consultant. The two volumes are the basis for planning detailed and adapted programs by educational and health authorities and by coöperating professional and lay groups in the community. They outline the general principles and specific objectives upon which each school system can develop suitable curriculum and organization to make health education effective.

Also from Kansas—this time from Dr. Leon R. Kramer, Director of the Division of Dental Hygiene—comes an impressive Dental Health Program for Elementary and Secondary Schools. Perhaps its most important line is in parenthesis—"with special emphasis on community planning."

A NEW STATE HEALTH BULLETIN IN MONTANA

Credit Lines has received the first

six issues of *Montana Health* which began in August, 1945, in celebration of the first birthday of the Montana Health League. This organization, made up of all the voluntary state health and medical agencies such as the Montana Hospital, Medical, Dental and Tuberculosis Associations, came into being in 1944 to fight a legislative proposal permitting osteopaths to practise surgery and medicine without limit in the state. Having learned the technique of coöperative action, it organized on a permanent basis and was effective also in campaigning for the permissive health unit law passed by the 1945 Legislature, a comprehensive Nurses' Practice Act, and establishment of a tuberculosis control division in the State Board of Health.

The first issue of *Montana Health* summarizes the purposes of the Health League, has an article by the State Epidemiologist, B. K. Kilbourne, M.D., on the new health unit law, another by the State Health Officer, W. F. Cogswell, M.D., on the organization of the State Board of Health, including an organization chart. Succeeding issues discuss a variety of public health and medical problems, presenting a variety of viewpoints.

THE NEW YORK MEDICAL SOCIETY
FIGHTS ANTIVIVISECTION BILL
INTELLIGENTLY

With the title, *Dogs, Drugs, and Doctors*, and the sub-title, *The March of Medical Progress will be Promptly Halted if Animal Experimentation is Prohibited by Law*, the New York State Medical Society issued a thrilling 35 page booklet that was valuable in opposing the recent Di Constanzo bill in the New York Legislature to restrict animal research. It contains a list of the medical problems that have been solved through research with animals as well as a much shorter list of unsolved problems requiring work with animals—

but these include cancer, leukemia, rheumatic fever, arthritis, and infantile paralysis.

The dramatic story is told of Dr. Victor Heiser's suggestion to test a proposed remedy for hookworm on a group of lobbying antivivisectionists at a Senate hearing in place of such testing on dogs. The ways in which a wounded G.I. of the late war was speeded to recovery and amputation prevented because of work previously done with dogs are reported. A careful understanding is built up of the care taken to avoid unnecessary pain to the animal—even more, that as careful operative and anesthetizing techniques as with humans are observed. Further, the benefits of animal research to animals themselves are explained, as in the case of black tongue in dogs.

Included with the pamphlet are two fliers, one listing the state senators and assemblymen with suggestions as to what to remind them of in this connection, and a reprint of Betsy Emmons' "The Case for Vivisection," another summary of the history and techniques of the antivivisectionists and of the work of Pasteur, Koch, Ehrlich, and many others whose work was aided by "man's best friend." The New York State Medical Society is to be congratulated for the effectiveness and high intellectual plane of its propaganda against what informed opinion everywhere regards as a misguided campaign.

LONDON IN 1944

The Interim Report of the County Medical Officer of Health and School Medical Officer for the year 1944 has just become available. It bears study, and with classic British understatement tells much of what can now be told as to rocket bomb damage. For example, "1944 was a trying year for Londoners." We find that no London County Council Hospital escaped damage, that a total of 5,000 beds were

destroyed and an additional 6,000 or 7,000 were temporarily out of action in a total of 660 "incidents"; that of 43,000 patients under treatment in Council hospitals at the end of 1944, 70 per cent were in mental hospitals, although the number declined over the previous year; that nutrition in the London schools was better than in 1938, that the death rate was 16.7 in contrast to 12.3 in 1939. In the meantime, however, it had risen to 18.7 in 1941 and fallen to 15.0 in 1942. An interesting page is one comparing population, birth and death rates, and other vital statistics in London and New York.

TRACHOMA CONTROL IN SAO PAULO

The story of efforts to control trachoma in the State of S. Paulo, whose population of about seven millions is more than one-sixth of all Brazil, is told in Dr. Silvio de Almeida Toledo's "The Struggle Against Trachoma in the State of Sao Paulo," published in 1944. It is detailed and comprehensive, charting the incidence of the disease and outlining the steps for its control, including a State Department of Trachoma, a Trachoma Research Institute, 34 dispensaries, and 20 rural units with their mobile sub-units that cover all the zones where the disease is prevalent. In 1943 nearly 55,000 persons were enrolled in these clinics and units. The author provides a short English summary of his volume which is written in his native Portuguese.

THE CHURCH SPEAKS UP FOR HEALTH INSURANCE

The Council for Social Action of the Congregational Christian Churches publishes a pocket size monthly called "Social Action." The November, 1945, issue is devoted to a discussion of national health insurance. Senator Pepper writes on "Legislation for Good Health": Dr. Charles L. Hyser, Chair-

man of the American Dental Health Association, on "The Way to Dental Health"; Dr. Allan M. Butler, Associate Professor of Pediatrics, Harvard Medical School, on "The Charity Tradition in Medicine"; Francis W. McPeck, Director of the Department of Social Welfare of the Washington (D. C.) Federation of Churches; on "If One Member Suffer . . ." They all add up to support of the Wagner-Murray-Dingell Bill.

"We need to move from the position that health is purely a personal matter to the insight that it is often a social one. This will involve modifications in the pattern of our medical services and in our concept of the relation between health and society." John Donne is quoted to the effect that "Any man's death diminishes me, because I am involved in mankind."

The pamphlet includes a good short bibliography of recent material on the subject.

OUR NEIGHBOR CONSIDERS VETERANS

The *Journal of the American Dental Association* started the New Year right by making its January, 1946, number a "Veterans Issue." It discusses opportunities for dentists in public health, in the U. S. Public Health Service, in industry, and in education and research.

The lead article, "Economic Considerations in Reestablishing a Dental Practice" analyzes the distribution of dentists throughout the country and relates that distribution to per capita income and size of community. The three states with one dentist per 5,000 or more persons are also three of the four states with 1940 per capita income of less than \$300 and the three with less than \$600 in 1943. Income of dentists is also discussed both in relation to age of dentist and size of community. Incomes were largest not in cities of 100,000 or more, but in those between 25,000 and 100,000. The

earning peak is reached in the years between 40 and 45 without regard to size of community. The number of persons per dentist is consistently in inverse relation to size of community. It is a thoughtful presentation, giving to the returning veteran dentist the background economic information on which he can determine his future location.

Other articles discuss educational opportunities and the G. I. Bill of Rights, summarize wartime legislation affecting dentists, changes in drugs, chemicals, prosthetic devices and dental materials during the war period, and indicate the services of the Bureau of Public Relations available to the veteran.

SPREAD THE WORK—AND THE FUN

Journal readers have already been told of the regional organization of Health Education Section committees (*Journal*, May, 1945, p. 516). Early in 1945 a questionnaire was sent to all members by the Section Secretary so that work on section projects could be widely assigned and in relation to the diversified training and talents of the members.

The replies of 46 members, 5 per cent of the total, to the request for suggestions for improving the Section program have recently been analyzed. The most frequent reply, though variously stated, boils down to "Give more of us an opportunity to participate in Section activities." This is what Charles Hendry called "involvement" in his discussion of several health education projects at the Annual Meeting of the New York City Public Health Association in 1945, and it is the lesson to be learned by other Sections of the Association, and indeed other associations.

The actual language of several replies is interesting—"Use member participation in making the basic philosophy and do not continue the practice of hit-or-miss papers presented by names,

each talking to his own interest. This is praiseworthy always, but does not build an integrated program." "More participation by all members. More opportunity for clinic and group discussion and fewer papers by 'experts.'" "If they are good articles, print, bind, and distribute them, but use annual meetings for more valuable discussion." "Give new blood a chance. Except for the last year or two, the Section has been dominated by the same old guard. This questionnaire gives me hope that others can get in their two bits worth." "Utilize members more. Many new members have useful ideas." "Rotate committee membership and officers more generally." "Why not look under some fresher bushel baskets?"

Other suggestions most often given are for more regional meetings, for more bulletins or news letters informing members of Section activities, and for the development of strong local branches. The late war comes in for mention by way of suggestion that visual education so rapidly developed during the war should receive more Section interest.

One more quote, "Accent zeal, purpose, and spirit and methodology will take care of itself. Academic degrees are not the end of the journey, but barely the setting out upon it."

RESTAURANTS KNOW THE MINNEAPOLIS HEALTH DEPARTMENT

Dr. D. C. Gates, Director of Health Education of the Minneapolis Health Department, sends a copy of a recent letter from the manager of the Minneapolis Restaurant Association to its constituent members. The moral is, "the Health Department is operating for you." He then tells them that the Department is constantly studying the problems of sanitation in its million and one phases, and suggests calling its staff in for recommendations as to improvement in restaurant organization and

sanitation. And he lists 13 achievements of the previous year affecting the whole community.

Dr. Gates also sends us three attractive leaflets announcing a free food handlers' school which emphasizes, with appropriate and funnier than funny-page drawings, "that the health of the people is *your* responsibility," one entitled "Facts about Diphtheria," and a third, a congratulation card for the new baby that announces the immunization schedule.

SANITARY REQUIREMENTS FOR SCHOOL LUNCHES

The Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association has recently published a statement describing the "Sanitary Requirements for School Lunches." Recognizing the importance of school lunches from the standpoint of nutrition and practical health education, the committee suggests protective measures to avoid contamination of food. Those measures are concerned with:

The condition, attire and conduct of the food handlers, condition of the premises and equipment, condition of the food, its preparation, care, and storage, including the special precautions to be taken with special types of food, and the supervision of personnel and premises.

The "ABC's of School Lunch Sanitation," and an essential list of questions with which the statement closes, should be in the hands of all lunchroom directors, principals, school physicians, school nurses, and health officers, as well as those directly handling food. Incidentally, the statement would be extremely useful in summer camps, industrial plant cafeterias, and in places where meals are served for short periods by inexperienced help, such as at county fairs, church suppers, and fraternal benefits.

Copies may be obtained from the

Chairman of the Committee, Thurman B. Rice, M.D., State Board of Health, Indianapolis 7, Ind.

WEST VIRGINIA IS HEARD FROM

"Safeguarding Your Health" is the title of a booklet telling about the community services of the Monongalia County Health Department. It serves a population of about 50,000, has been a full-time county unit since 1929, became a Public Health Training Center in 1936, and moved into a permanent health center building in 1944. The story is well told and illustrated.

PREMARITAL LAWS

We are indebted to Dr. Claude P. Brown, Assistant Director of the Pennsylvania Department of Health Laboratories for a copy of the November 1945 *Pennsylvania's Health*. This contains a compilation of premarital laws of the various states, prepared by the laboratories for the use of the doctor consulted by the bride and groom. We are informed that additional copies are available.

ADVERTISING FOR HEALTH OBJECTIVES

The *New York Times* of January 30, 1946, has an illustration of a significant new technique of securing public attention for a health objective. Under the title, "More Important Than Reaching the Moon: Child Health," the International Latex Corporation, in two columns of paid advertising, reprints a *Washington Post* editorial in favor of Senator Pepper's proposed Maternal and Child Welfare Act.

SERVICES FOR UNMARRIED MOTHERS

A joint statement on *Services for Unmarried Mothers and Their Children* has been prepared by the Children's Bureau, Bureau of Public Assistance (Social Security Board) and the American Red Cross. It is an 18 page booklet describing the present situation, the

plans and resources to meet the needs. Its purpose is to encourage coördinated planning and action to provide the needed service. Copies may be obtained from the Superintendent of Documents, Gov. Ptg. Off., Washington, D. C. Price, 10 cents.

WORTH ACQUIRING

No, No, a Thousand Times No—An illustrated leaflet, for use in well child conferences, that suggests many simple ways of reducing the number of noes a child receives. Play space of his own, precious or fragile knickknacks out of reach, and time to learn are all suggested, in the interest of the child's mental health. Bureau of Maternal and Child Hygiene, Hartford Health Department, Hartford 4, Conn.

Food and Nutrition—Prepared jointly by the State Departments of Health and of Education and four rural county schools as a textbook for teachers and pupils in California. Gives not only the basic principles of nutrition but also a brief history of man's quest for food and several appendices, including calorie tables for different foods and an extensive bibliography classified separately for teachers and children. California State Department of Education, Sacramento, Calif.

Books on Home and Family Living—Michigan Public Health of October, 1945, publishes this list prepared by the Michigan Department of Health's consultant in Parent Education. It lists both books and magazine articles, classifying them according to the various periods between infancy and maturity. State Department of Health, Lansing, Mich.

A Man's Castle—A National Pro-

gram for the Prevention of Home Accidents. Sponsored by 31 organizations from American Association for Adult Education to Zonta International, and including the American Public Health Association, this attractive booklet, liberally illustrated in red, tells all about home accidents. They kill 30,000 persons a year of whom 6,000 are under school age; fires in homes cost over a million dollars a year. Accidents can be reduced by community action, by proper house construction, design, and furnishing, by safe equipment and by education through newspapers, magazines, radio, and motion pictures. The goal—"Home is where all members of the family should always be able to find comfort and convenience, health and security, freedom from danger." Available without charge from the National Safety Council, 20 N. Wacker Driver, Chicago 6, Ill.

Twenty-five Years of Effort and Service—A silver anniversary report in a silver cover, and with excellent typography and illustrations, this description of the Cincinnati Public Health Federation (Bleeker Marquette, Executive Secretary) has fertile ideas for reporting on community stewardship. Public Health Federation, Cincinnati, Ohio.

A Guide for Nurses in the Nursing Care of Patients with Infantile Paralysis—a revision prepared by the Joint Orthopedic Nursing Advisory Service of National Organization for Public Health Nursing and the National League of Nursing Education. Published and distributed without charge by the National Foundation for Infantile Paralysis, 120 Broadway, New York 5, N. Y.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

When You Marry—By Evelyn Millis Duvall and Reuben Hill. New York: Association Press, 1945. 450 pp. Price, \$3.00.

The authors of this volume are respectively on the staff of the National Conference on Family Relations and the Department of Sociology, Iowa State College. The foreword by Professor Ernest W. Burgess of the University of Chicago points out the timeliness of this functional approach to the teaching of marriage and family living. As he says, American youth by the hundreds of thousands are concerned as never before with problems of adjustment, often growing out of the large number of hasty marriages, but also from the group who have postponed marriage.

The book includes four parts, Anticipating Marriage, What It Means to Be Married, The Making of a Family, and Family Life Yesterday, Today and Tomorrow. Appendices include a Marriage Prediction Scale that fascinates adolescents and a list of recognized marriage and family counseling services.

The authors maintain that marriages which have been preceded by study and careful mate selection, and which are followed by skillful handling of adjustments, have high success rates. The book is best suited for reading and discussion at the college level, but also has meaning for high school groups under good leadership. The text is in easy style, well illustrated, interspersed with test questions set up in provocative form, and with excellent suggestions for further study.

Adolescents will profit by reading such chapters as that entitled "Dating: Practice Makes Perfect"—subtitles include, What to do on a date; Going Steady; How to break off with a Steady; Dating is Preparation but it is also Fun; What about Petting? etc. Especially well done from the mental hygiene angle is "Common Conflicts in Marriage."

This volume, in the opinion of the reviewer, represents the best of its class and marks a new achievement in what may be called sex hygiene in its most inclusive sense.

REGINALD M. ATWATER

Safe and Healthy Living—By J. Mace Andress, Ph.D., I. H. Goldberger, M.D., Margaret P. Dolch, and Grace T. Hallock. New York: Ginn & Company, 1945.

Book I—Spick and Span, 152 pp. Price, \$.84.

Book II—The Health Parade, 184 pp. Price, \$.88.

Book III—Growing Big and Strong, 252 pp. Price, \$.92.

Book IV—Safety Every Day, 258 pp. Price, \$.92.

Book V—Doing Your Best for Health, 298 pp. Price, \$.96.

Book VI—Building Good Health, 298 pp. Price, \$1.00.

Book VII—Helping the Body in Its Work, 314 pp. Price, \$1.04.

Book VIII—The Healthy Home and Community, 339 pp. Price, \$1.08.

This new edition of health textbook series for grades one to eight presents in typical fashion the most recent material on health and safety for class-

room instruction. The books are well illustrated with photographs of appropriate age groups in healthful experiences. Sketches and diagrams also enliven the printed word. The chapters are developed in the form of Units of Instruction. Each unit contains basic information, often in story form, questions for thought and discussion, tests, suggested activities, and a general word study exercise. A list of other books to read, a dictionary of health words, and a word index make valuable additions to the volumes.

The list of titles for each book are an indication of the enlivened contents. "Spick and Span," "The Health Parade," and "Growing Big and Strong" are apt titles for the early elementary grades. The titles for the fourth, fifth, and sixth graders offer increasing responsibility for the increasing years: "Safety Every Day," "Doing Your Best for Health," and "Building Good Health." The later elementary or junior high titles place greater emphasis upon home and community living, "Helping the Body in Its Work," and "The Healthy Home and Community."

These textbooks are written largely for the city school child with a good background of home and community living. Lack of understanding of many rural problems of living are evident. Like all school textbooks this series presents the accepted standards of health, and seldom helps the pupils to take what they have and build toward a more healthful way of living within their own environment. For the most part the suggested activities deal with real life situations and not the earlier fairy-story-busy-work type of activities. It is to be regretted that many of the references in the list of books to read, which appears in each volume, are not as modern and up-to-date as the general contents of the books themselves.

REBA F. HARRIS

Scientific Societies in the United States—By *Ralph S. Bates, Ph.D.* New York: Wiley, 1945. 246 pp. Price, \$3.50.

The reader of this volume will find not a directory in the usual meaning of the term, but an interesting account of the history and influence of scientific societies in the United States, including not only those of national scope but many state and local societies as well.

It is a general survey of the pattern of development of scientific organizations.

The material is divided into four periods: 18th century, 1800–1865, 1866–1918, 1919–1944. For each period the author depicts the main scientific trends and describes the beginnings and functions of the societies developing from the background of that period.

There is an extensive bibliography and also a good index.

EVA R. HAWKINS

Vitamins and Hormones — *Advances in Research and Applications. Vol. III. Edited by Robert S. Harris and Kenneth V. Thimann.* New York: Academic Press, 1945. 420 pp. Price, \$6.50.

This is the third volume of a series under the same title started in 1943 with the purpose of reviewing and appraising research in these fields. It is almost essential in these days of voluminous scientific literature to have a specialist evaluate the status of a subject and point out gaps and controversial issues with suggestions for further research. This is exactly what the authors of the nine articles in the present volume have done in well organized and completely documented form. The subjects covered in the present articles do not duplicate those of the previous volumes, although there is bound to be some overlapping even in the articles in this volume when

different authors discuss closely related subjects.

The titles and authors of the nine articles in Volume III are: The Interrelation of Vitamins by Moore; The Synthesis of B Vitamins by Intestinal Bacteria by Najjar and Barrett; Sulfonamides and Vitamin Deficiencies by Daft and Sebrell; Manifestations of Prenatal Nutritional Deficiency by Warkany; Growth Factors in Microbiology by Knight; Possibilities in the Realm of Synthetic Estrogens by Dodds; Chemistry of Anti-pernicious Anemia Substances of Liver by Subbarow, Hastings and Elkin; Mechanism of Action and Metabolism of Gonadotropic Hormones in the Organism by Zondek and Sulman; The Rôle of Acetylchlorine in the Mechanism of Nerve Activity by Nachmansohn.

This volume should be a valuable reference to help research workers and teachers in biochemistry, physiology, endocrinology, microbiology, nutrition and related medical sciences keep in touch with work reported in a wide variety of journals. HELEN S. MITCHELL

Your Child from One to Six—
Publication 30, Children's Bureau (rev. ed.). U. S. Department of Labor, Washington: Supt. of Documents, 1945. 147 pp. Price, \$.15.

This is a complete revision of *The Child from One to Six*, a booklet, widely used in this and other countries since it was last rewritten in 1931.

The greatest difference between the previous and the new edition is a difference of approach rather than one of content. It reflects the trend of the past ten years in which the yardsticks applied to the growth and development of children have become more flexible and the "musts" of a child's performance at certain ages have become fewer.

Family relationships and their importance for all phases of the physical and mental development of children are stressed in each of the 29 chapters which are logically subdivided and cover the most important aspects of growth and development of preschool children. The language is clear, the print more liberally spaced and the text, illustrated by excellent photographs, should hold the interest even of those parents who are not accustomed to serious reading. This up-to-date and attractive booklet will be a popular educational tool in the hands of physicians, nurses, and other workers in the field of child care. One should be able to find it in all libraries, clinics, doctor's offices, and public health nursing bags.

FRANZISCA W. RACKER

Cleveland Market Data Handbook
—By Howard Whipple Green. *Cleveland: Real Property Inventory of Metropolitan Cleveland, 1945. 69 pp. Price, \$2.50.*

This volume has been published under the direction of Howard Whipple Green, who is Secretary and Director of Statistics and Research, Cleveland Health Council, Cleveland, Ohio, and represents a unique and compact reference book of pertinent facts about Cleveland, including data on population, cost of living, employment and unemployment, telephones, automobile sales and registration, postal receipts, bank deposits and other financial data, new construction, mortgage finance, public finance and taxation. A series of tables and charts presents this material for the 35 year period since 1910.

The reviewer wishes that comparable data were available for all the larger cities and states, because they are essential in any comprehensive approach to public health.

REGINALD M. ATWATER

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

How Much Do Children Eat?—Three researchers have been measuring the increasing amounts of food that children manage to stow away during the years from infancy to age 10, and they find that the allowances set by the Food and Nutrition Board do not match up to the performance of children in middle class families. The researchers found a lot else, but that is one item that may stick in your memory.

BEAL, V. A., *et al.* Nutrition Studies on Children Living at Home. *Am. J. Dis. Child.* 70, 4:214 (Oct.), 1945.

Commended for Its Wisdom—Shall we teach the "facts of life" or that sex is bound up in emotion? A British writer makes the following daring assertion: "For my part I *do* believe that certain aspects of sex and sex behavior are sometimes rather ludicrous, that sex may sometimes quite properly be the occasion of humor, and I would therefore emphasize the importance of avoiding the sin of hypocrisy."

BIBBY, C. Sex Education. *Med. Officer.* 74, 23:187 (Dec. 8), 1945.

Removing Some of the Mystery—As in the country, so in the city, poliomyelitis is spread principally by patient to patient contact. In a painstaking study carried out in Chicago last summer, the infection was found to be as contagious for toddlers as are the other diseases of childhood. The researchers unearthed no evidence that insects played a rôle in the spread of the disease.

CASPY, A. E., *et al.* Transmission of poliomyelitis by Patient to Patient Contact (and two related papers). *J.A.M.A.* 129, 17:1141 (Dec. 22), 1945.

Better Health for Americans—Though the ideas stem from the cloistered precincts of a medical school, it is refreshing to see in one of our medical journals a dispassionate presentation of these four problems: distribution of treatment facilities, payment for medical services, organization of such services, and economic opportunities for physicians. This is the first paper of what promises to be a rewarding symposium.

CLARK, D. A. Problems of Medical Care. *New England J. Med.* 234, 2:53 (Jan. 10), 1946.

"This Fight for Health . . ."—Canada's plans for a more effective health service and a system of health insurance are presented in some detail. Canadians seem to be quite prudent people, much like ourselves, yet they go ahead with their prepaid medical care scheme with no evident worry about its undermining their ordained way of life or concern about whether or not it is communistic in origin.

CLAXTON, B. Mapping Our New Frontiers of Health. *Canad. Pub. Health J.* 36, 12:455 (Dec.), 1945.

Wild Prediction Department—What do you suppose would happen if an agency issued a completely honest report, accurate and penetrating as an x-ray, listing failures as well as accomplishments and straddling no controversial issues—even the one of need for the agency's own program? The writer makes this prediction: of course, the executive would be fired, but if the trustees did not burn every copy, the public response would be amazing.

CROSBY, A. L. Toward Better Annual Reports. *Channels.* 23, 3:1 (Dec.), 1945.

Earmarks of a Crisis—This brief excerpt tells a long story: "... while the over-all rate of acquisitions of new (venereal) infections by all Navy men has dropped substantially from pre-war levels, the trend for 1945 is up—and drastically so..." What the Navy is doing with the candidates for infection while still in uniform and the parallel civilian plans are things you should know about.

FERREE, J. W., and ENNES, H. The Venereal Disease Heritage of World War II (and) HELLER, J. R. The Postwar Syphilis Control Problem in the United States. *J. Soc. Hyg.* 31, 8:515 (Nov.), 1945.

Here's a Treat—The man who had the God-given curiosity to examine a phenomenon which many other bacteriologists must have seen and ignored, tells about his part in the production of the drug that is doing most to change the complexion of public health administration.

FLEMING, A. The Story of Penicillin. *Mod. Med.* 13, 12:57 (Dec.), 1945.

Complete Health Service—The Permanente Health Plan proves that medical care can be furnished within the means of the average American, and if it is offered to him that same mythical Mr. A. A. will rush to subscribe for it in advance. The writer says he knows this is so because he and his colleagues have offered the service.

GARFIELD, S. R. The Plan That Kaiser Built. *Survey Graphic.* 34, 12:480 (Dec.), 1945.

Freezing Kills Them—How can trichinosis be prevented? Microscopic inspection of carcasses has been tried and found wanting. Cooking city garbage would help but not stop spread to all pigs. The deep freezing of all pork products for human consumption might do the trick. As one in six of us gets an infestation at one time or another it would seem that any likely method should be tried.

GOULD, S. E. An Effective Method for the Control of Trichinosis in the United States. *J.A.M.A.* 129, 18:1251 (Dec. 29), 1945.

We Need To Know the Normal—Are low-blood pressure and low hemoglobin chiefly responsible for the fatigue that young women suffer? Many are told so, and treated for these conditions. This study of "normal" girls in Cambridge suggests that these are not the real causes of "that tired feeling."

HARDY, H. L. The Clinical Significance of Data Accumulated in Medical Care of Young Women. *New England J. Med.* 233, 26:811 (Dec. 27), 1945.

Still Held at Belsen—Intimate impressions are given about the long-range problems of the Stateless Nazi victims who have no home to go to and wouldn't dare to go there if they had. Pictured too are the hideous hygienic conditions they survived.

HARRISON, E. G. The Last Hundred Thousand. *Survey Graphic.* 34, 12:469 (Dec.), 1945.

Calculated Crimes—Here is told how the British medical officers dealt with the terrified horde of liberated D.P.'s who—lousy, diseased, and starved—rushed for the Rhine. The picture of the hygienic conditions from which they escaped will make you sick.

HARVEY, W. C., and MARKOWE, M. The Rhine River Barrier (and) MANN, B. Hygienic Problems in Displaced Persons' Camps in Germany. *Pub. Health.* 59, 3:31 (Dec.), 1945.

Teeth Are To Chew With—Blaming dietary deficiencies for modern man's defective teeth has no scientific basis argues this writer. If this were so, present-day diet would have had an adverse effect upon the whole body. Yet we know that civilized men are greatly superior to primitives. No, the teeth are poor because we don't use them, and how to induce us to put them to work is a poser.

KLATSKY, M. Function versus Nutrition as a Controlling Factor in Dental Health: An Anthropologic Survey. *J. Am. Dent. A.*, 32, 21:1416 (Dec.), 1945.

For Thin and Fair Skins—Holding that this department might well be put occasionally to some useful purpose, we pass along to you the information that one application of dark red veterinary petrolatum will give complete protection against sunburn for a whole day and water will not wash it from the skin.

LUCKJESH, M., *et al.* Protective Skin Coatings for the Prevention of Sunburn. *J.A.M.A.* 130, 1:1 (Jan. 5), 1946.

Upgrade, Peak, and Downgrade—Contagiousness, argue these writers, is not a fixed characteristic of tuberculosis. In a highly tuberculized environment, the disease is not a contagion. In not-yet-tuberculized or de-tuberculized environments, tuberculosis is contagious. The legal implications of this thesis are discussed.

MAYER, E., and RAPAPORT, I. Is Tubercu-

losis Contagious? Compensation Medicine. 1, 1:5 (Jan.), 1946. (Note the 1:1 please!)

What an Expectant Health Worker Should Know—Plenty of jobs are available in public health for those who are adequately trained for them. The meaning of adequate training for the medical graduate constitutes the burden of this paper which also paints an inviting picture of the opportunities and responsibilities.

PARRAN, T. Opportunities for the Medically Trained in Public Health. *J.A.M.A.* 129, 17:1161 (Dec. 22), 1945.

Little Rhodie Pioneers—This is mostly about the Rhode Island Sickness Compensation Act and the reasons other states have not followed suit, but it contains a list of bills on compulsory sickness insurance introduced in, and ignored by, the various state legislatures over the past five years.

STUCKE, A. Notes on Compulsory Sickness Insurance Legislation in the States, 1939-44. *Pub. Health Rep.* 60, 52:1551 (Dec. 28), 1945.

ASSOCIATION NEWS

SEVENTY-FOURTH ANNUAL MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION
CLEVELAND, OHIO — NOVEMBER 11

RESOLUTION ENDORSING CONTROLLED ANIMAL EXPERIMENTATION

Adopted by the Executive Board of the American Public Health Association
January 25, 1946

The public health professions have noted current legislative efforts to prohibit the use of animals for scientific medical research.

The American Public Health Association, representing those who are intimately engaged especially in the application of medical science, strongly endorses the continued use of controlled animal experimentation. Such unhampered experiments we know to be essential for continued medical progress.

The public should be fully aware of the consequences which would follow the enactment of any legislation forbidding the use of dogs or other animals for experimental purposes under responsible direction, such as that in the universities and medical schools. It is common public knowledge that a large part of the recent advances in protect-

ing the health of children grows out of the use of dogs for experimental purposes.

We know that the surgeon's skill goes back to operations which he has repeatedly made as a student under supervision in the medical school.

Is it desirable, for instance, that new drugs or new surgical technics should be tried first on babies or on dogs?

It is inconceivable in this day when the benefits of science are so manifest that the people will wish to shackle the hands of those whose chief concern is the lengthening of life and the prevention of disease.

We call upon all intelligent citizens who have the public interest at heart to oppose openly any attempts to restrict the essential freedom of scientific research.

DR. ROSCOE P. KANDLE APPOINTED ASSOCIATE FIELD DIRECTOR

The Executive Board of the American Public Health Association has announced the appointment of Roscoe P. Kandle, M.D., M.P.H., Fellow, A.P.H.A., as Associate Field Director on the staff of the Committee on Ad-

ministrative Practice. Dr. Kandle began his field assignment in January, working first on the survey of the Colorado State health services with Carl E. Buck, Dr.P.H., Field Director.

Dr. Kandle graduated from Jefferson Medical College, Philadelphia, in 1934 and from the Johns Hopkins School of

Hygiene and Public Health in 1938. He served for four years on the staff of the New Mexico State Department of Health, for a short time with the New Jersey State Department of Health, and since 1940 has been identified with public health administration in Louisiana, most recently as the Director of the Division of Local Health Services.

Dr. Kandle's responsibilities will be similar to those carried for several years past by George T. Palmer, Dr.P.H., now Senior Sanitarian (R), U. S. Public Health Service, Washington, D. C. His special assignment will be in connection with state health studies and the use of the Evaluation Schedule by state and local departments of health and in the periodic publication by the Committee on Administrative Practice of *Health Practice Indices*.

Roscoe P. Kandle

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- Lt. C. Dale Barrett, Jr., M.C., WDPC, A-3, Fort Devens, Mass., Director, Ottawa County Health Dept., Grand Haven, Mich. (upon release from service)
 Wayne G. Brandstadt, M.D., Johns Hopkins Univ., School of Public Health, Baltimore 5, Md., Student
 Sheldon M. Caplan, M.D., 208 E. 21 St., Chester, Pa., Senior Asst. Surgeon (R), U. S. Public Health Service
 Andrew H. Dibble, M.D., Central Louisville Health Center, 1125 Cedar Court, Louisville, Ky., Director
 Malcolm J. Ford, M.D., Johns Hopkins Univ., School of Public Health, Baltimore 5, Md., Senior Asst. Surgeon, U S Public Health Service
 James P. Jones, M.D., Ritchie County Health Dept., Pennsboro, W. Va., Health Officer

NEW A.P.H.A. ACTIVITIES IN MEDICAL CARE

Implementing "Medical Care in a National Health Program," an Official Statement of the American Public Health Association adopted in October, 1944, the Committee on Administrative Practice announces the expansion of its Subcommittee on Medical Care and new plans for continuation of this important program.

A grant from the Rockefeller Foundation now makes possible the employment of a much needed full-time staff for the work of this committee. Howard M. Kline, Ph.D., of the Procurement and Assignment Service, Federal Security Agency, and the staff of the U. S. Public Health Service, has accepted the position of Technical Secre-

tary, and other staff persons are being assembled to carry on a project which has four major aims:

a. To formulate in considerable detail the specifications of a suitable medical care program, and to set forth with definitiveness the successive steps by which such a program should be brought into being, and further to formulate detailed proposals for the organization, financing, and administration of a program;

b. concurrent with (a) to evaluate the experience of existing medical care programs, thus laying the basis of factual knowledge necessary for solution of the problem;

c. To review proposed federal and state health legislation in the light of declared principles and to recommend

to the Association a stand with respect to such legislation;

d. To aid in informing public health personnel as to medical care problems and to stimulate the assumption of leadership in the formulation and administration of medical care programs.

For the purposes of this expanded program, the Subcommittee on Medical Care has been enlarged. Its membership now includes:

Joseph W. Mountin, M.D., *Chairman*
Chief, States Relation Division
U. S. Public Health Service

Dean A. Clark, M.D.
Medical Director
Health Insurance Plan of Greater New York

Edwin F. Daily, M.D.
Director, Division of Health Services
U. S. Children's Bureau

Isidore S. Falk, Ph.D.
Director, Bureau of Research and Statistics
Social Security Board

Vlado A. Getting, M.D.
Massachusetts State Commissioner of Public Health

J. Roy Hege, M.D.

Director, Division of Local Health Administration

North Carolina State Board of Health

University of Michigan

R. M. Walls, D.D.S.

Dental Practice, Bethlehem, Pa.

John B. Grant, M.D., Consultant

Rockefeller Foundation

Hugh R. Leavell, M.D., Consultant

Rockefeller Foundation

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing Officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y.

Vacant Positions Listed with the Association's Vocational Counseling and Placement Service

As this issue of the Journal went to press, the Vocational Counseling and Placement Service of the American Public Health Association, 1790 Broadway, New York City, had listed 96 positions for physicians in public health in administration, epidemiology and in the clinical field. Nine positions were offered to non-medical administrators, 2 to public health dentists, 27 to health educators, 10 to laboratory workers, 12 to sanitary engineers, 1 to an industrial engineer, 12 to sanitarians, 4 to statisticians, 1 for a nutritionist and 5 for medical social workers. A total of 180 positions offered by 86 employers were currently listed. One hundred and twenty-five applicants in all categories were in the record. This represents a substantial increase from the figures of one month previous. Only a part of these openings are covered in listings on the employment page of the *American Journal of Public Health*. Employers and candidates interested should communicate with the Vocational Counseling and Placement Service at the above address.

As previously announced, this service is rendered without charge by the Association, which is assisted for this purpose by the U. S. Public Health Service in a jointly sponsored project carried on under the auspices of the Committee on Professional Education, of which William P. Shepard, M.D., of San Francisco, is Chairman. It is the aim of this service to place at the disposal of all persons now seeking positions in public health the counsel of those well informed in the field, with a special effort to assist veterans. Public health nursing positions are not listed by the A.P.H.A. but inquiries are forwarded to the N.O.P.H.N. and other nurse placement agencies.

POSITIONS AVAILABLE

(Supplemental to list in February Journal)

Wanted: Physician trained in tuberculosis to assume permanent control of Tuberculosis Division of Health Department of Eastern city of 185,000. Applicant please state salary expected. Apply Box H, A.P.H.A.

Opportunities Available

WANTED—(a) Director of division of maternal and child health and, also, epidemiologist and director of division of preventable disease control; former position requires general public health training and some experience in maternal and child health work; latter position requires experience and training in epidemiology especially venereal disease control; well organized city health department, seven divisions; staff of 54 employees; Middle West. (b) Director of division of tuberculosis control; state department of health; tuberculosis specialist with administrative experience required; duties include serving as consultant of several sanatoria and, also, building of five tuberculosis hospitals; South. (c) Director of crippled children's program; pediatrician with public health experience or training preferred; department responsible for providing medical and surgical care of approximately 5,000 children; well staffed department, rapidly growing; permanent headquarters in university medical center; Middle West. (d) Student health physician; enrollment of 5,000 students; more than 400 on faculty; well equipped department; Pacific Coast. (e) Public health physician to serve as county health officer; duties consist of supervising school immunizations, epidemiology, venereal disease clinics and well baby conferences; well staffed department; California. (f) Public health physician to direct program for cancer control; preferably someone experienced or particularly well trained in cancerology; should be capable public speaker and able to qualify for teaching appointment on faculty of university medical school. PH3-1 The Medical Bureau, Burneice Larson, Director, Palmolive Building, Chicago 11.

WANTED—(a) Public health nurse with extensive training and experience to accept interesting assignment in Central and South America; though knowledge of Spanish or Portuguese desirable, will consider someone willing to learn either language. (b) Supervisor and staff nurses; visiting nurses' association; supervisory position requires year's graduate training in public health nursing and experience under qualified supervision; New England. (c) Executive director; one of the leading agencies for generalized nursing located in suburb of Eastern city, immediately. (d) Director, supervisors and staff nurses

to join staff of national health association; considerable traveling; salaries for staff positions dependent upon qualifications but not less than \$2,100; salary for supervisors \$2,980 plus \$6 a day when away from headquarters; salary for director dependent upon qualifications; headquarters in Middle West and Southwest. (e) Public health nurse for executive position in high school and junior high school; vicinity of Chicago. (f) Instructor and supervisor of public health and outpatient nursing; large teaching hospital, outpatient department used for instruction of medical students; active teaching and research program; baccalaureate degree and public health preparation required; \$225. PH3-2 The Medical Bureau, Burneice Larson, Director, Palmolive Building, Chicago 11.

WANTED—Sanitarian to direct plant and production; sanitation program of one of the country's most important food industries; must be soundly grounded in fundamentals necessary to well rounded sanitary program for food industry; capable public speaker required. PH3-3 The Medical Bureau, Burneice Larson, Director, Palmolive Building, Chicago 11.

WANTED—(a) Health educator; new public health program, emphasizing venereal diseases and social hygiene; previous experience in conducting health education program required; \$3,600-\$4,800; Southwestern city of 200,000. (b) Health educator; tuberculosis association and city health department; East. (c) Health educator; city-county health department; college town of 60,000; Middle West. (d) Assistant educational director; Chicago offices of national organization; \$3,000. PH3-4 The Medical Bureau, Burneice Larson, Director, Palmolive Building, Chicago 11.

WANTED—(a) Several bacteriologists and serologists for public health laboratories; state department of health; rank and salaries dependent upon experience in public health laboratories; South. (b) Senior and junior bacteriologists; state department of health; senior position requires tuberculosis experience; Middle West. PH3-5 The Medical Bureau, Burneice Larson, Director, Palmolive Building, Chicago 11.

Opportunities Wanted

Young physician with intimate knowledge of all aspects of industrial hygiene and medicine is available; past several years, director of department of industrial hygiene, state department of health; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Public health physician; degrees of Doctor of Medicine and Master of Public Health from Middle Western university; has been in full-time health department work since 1939 where his duties have been principally in administrative capacity; age forty-four; will go anywhere; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Dentist who has specialized in public health; D.D.S., university medical school; several years' private practice; year of postgraduate training in public health hygiene with special emphasis on public health dentistry for which he received degree of M.S.P.H.; several years, state department of health; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Health educator; A.B., M.S. degrees, middle western university; experience largely administrative including eight years as associate professor of medicine, co-educational college; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

NEWS FROM THE FIELD

THE PLAN OF DISTRIBUTION BY THE AMERICAN RED CROSS OF THE DRIED BLOOD PLASMA DECLARED SURPLUS BY THE ARMED FORCES

During the war, large quantities of blood were given by the American people through the American Red Cross from which dried plasma was prepared for the armed forces. The supply of this material was predicated upon the needs of the Army and the Navy for a long and costly war. Because of an earlier cessation of hostilities than was reasonably to be expected in both the European and Pacific Theaters, there is now in the hands of the Army and the Navy a quantity of dried plasma which is in excess of their needs during the anticipated useful life of the plasma, namely, 5 years from the date of processing. Accordingly to Army and Navy estimates, the available surplus amounted to approximately one and a quarter million packages at the end of December.

The transfer to the American Red Cross of dried plasma declared surplus by the Army and the Navy is provided for by Public Law 457 of the 78th Congress, approved October 3, 1944. The pertinent portion of this law, Section 11 (f), reads as follows:

"No surplus property which was processed, produced, or donated by the American Red Cross for any government agency shall be disposed of except after notice to and consultation with the American Red Cross. All or any portion of such property may be donated to the American Red Cross, upon its request, solely for charitable purposes"

Under the foregoing provision of Congress, a formal request was made to the Army and the Navy that all surplus plasma be transferred to the American Red Cross. This action was taken on the ground that the American

Red Cross has a responsibility to the American people to assure that plasma and other derivatives of the blood voluntarily contributed for the members of the armed forces be utilized to the best advantage and not wasted or offered for sale or barter. In making this request, it was proposed that any surplus should be returned to the American people, who had made these supplies of plasma possible, for use in veterans hospitals and in civilian medical practice. This proposal was accepted by the Army and the Navy and accordingly they will transfer to the American Red Cross all available surplus stores of plasma and other blood derivatives.

In developing a plan for the distribution of this material it was felt that the first consideration was that the needs of the Veterans Administration be met. This was discussed with General Hawley, and it was arranged to provide him with the amount of plasma estimated will be required for use in Veterans Administration facilities during the next five years.

In planning for distribution and use in civilian medical practice there were three factors believed to be of particular importance. The distribution should be carried on in such a manner as first, to assist in making possible an accurate determination of the needs for blood and blood derivatives in the various parts of the country; second, to strengthen and stimulate the development of already established state and local civilian blood and blood derivatives programs; and third, to demonstrate the value of such programs and thus stimulate their establishment where they do not already exist.

The surplus dried plasma amounts to about one and a quarter million

packages, which it is estimated will meet civilian needs for approximately two years. Warehouse storage space is provided in each of the five Red Cross areas, the headquarters of which are located at New York City, Alexandria, Va., Atlanta, Ga., St. Louis, Mo., and San Francisco, Calif. The available plasma will be apportioned to each of these areas on a population basis, and supplied to state departments of health for distribution without charge to all physicians licensed to practise medicine, and to all acceptable hospitals for use in the treatment of any patient without charge for the product. This plan is similar to that which the state departments of health have been following in distributing the surplus immune serum globulin made available by the American Red Cross for the prophylaxis and modification of measles.

The area medical directors of the American Red Cross will make arrangements with state departments of health for a satisfactory plan for the distribution of plasma within each state, in consultation with representatives of the state medical society and state hospital association. The American Red Cross will then make an initial shipment to the health department in an amount estimated to be a 3 months' supply. This estimate will be based on the population of the state, weighted by the number of physicians and the number of general, pediatric, and maternity hospital beds. Thus, every physician may, if he desires, carry plasma with him, and hospitals may be stocked with a reasonable supply for the treatment of their patients. Replacements of plasma may be obtained on request by physicians or hospitals from the state department of health, or through the local Red Cross chapter, if the department of health does not have a local distribution center. State departments of health in turn will obtain replacements of plasma up to a 6 months' supply by requesting

it from the area office of the American Red Cross.

LOCAL HEALTH UNITS IN ILLINOIS INCREASE

The January, 1946, *Illinois Health Messenger* of the Illinois Department of Health reports that 14 counties have organized locally managed and financed county health departments since the passage of the permissive Searcy-Clabaugh health unit law in 1943. The 14 counties are served in 11 units, nine of one county, and one each of two and three counties.

In several instances where the populations are less than 40,000, a neighboring county may later join the unit, in accordance with the recommendations of the State Health Officer and the A.P.H.A. Committee on Local Health Units, as contained in *Local Health Units for the Nation*, recently published by the Commonwealth Fund.

INDUSTRIAL HYGIENE NEWS ROUND THE GLOBE

The JOURNAL is indebted to the November and December *Industrial Hygiene News Letter* for the following items selected from many of interest:

"British and Brazilian Industrial Hygienists Study U. S. Methods—Reflecting the growing interest in industrial health within their nation, Drs. R. S. F. Schilling and Donald Hunter of the British Medical Research Council, and Dr. George S. Bandeira de Melo of Brazil are at present in the United States studying American industrial hygiene practices.

"Yale to Teach Industrial Medicine—Plans for the establishment of a training institute of occupational medicine and hygiene have been announced by the Yale University School of Medicine. Undergraduate medical students will be trained in the basic approaches to occupational medicine throughout all four years of their

course. The curriculum will include instruction in sanitation, toxicology, traumatic surgery, shock treatment, rehabilitation methods, occupational diseases and their treatment, problems of ventilation, industrial medical administration, and other subjects.

"Graduate instruction in the Institute will be available to physicians working in industry, and further training will be open to industrial nurses. The Institute will carry on research in industrial health problems, and give consultative service to industry.

"Children Poisoned by Burning Battery Cases—The latest case of persons suffering lead poisoning as a result of using discarded battery cases for fuel reported to the Industrial Hygiene Division, U. S. Public Health Service, is that of five children in one family who were made seriously ill when battery cases were used to eke out the scanty coal supply in their home.

"Industrial Hygiene in the War-torn Philippines—Dr. Gregorio D. Dizon, Philippine Bureau of Health, writes of his studies in dermatitis due to arsenic poisoning in a large copper mine in the islands—studies interrupted by the late war. He also studied mass benzol poisoning at the Cavite Naval Base during the Japanese occupation, but the records were burned by Japanese after the fall of Manila.

"The loss of his industrial hygiene literature and records, most of them burned, is felt keenly by Dr. Dizon. He appeals to members of the A.I.H.A. to send whatever can be spared to start a new library.

"Polarograph in Oregon—Dr. Harold M. Erickson, Oregon State Health Officer, reports that the Division of Industrial Hygiene has acquired a Heyrovsky Polarograph, the only one of its kind at present on the Pacific Coast. This instrument can be used for determination of minute quantities of toxic mineral contaminants of work-

room atmosphere. Local health units and other state departments have been invited to make use of the polarograph as needed.

"Virginia Coal Mines Study Hazards—Environmental exposures and conditions in a Virginia coal mine are being studied by the Bureau of Industrial Hygiene, of the State Department of Health. Preliminary study and a few atmospheric samples indicate a potential high exposure to coke and coal dust, sulfur dioxide, hydrogen or sulfide, and extreme temperature changes. More detailed investigation has been undertaken. Request has been received from another coal company, asking for environmental survey of conditions in their mines."

THE MAYO PROFESSORSHIP IN PUBLIC HEALTH

The University of Minnesota has announced that its first permanently endowed professorship has been created as the Mayo Professorship in Public Health under an endowment by the Mayo Properties Association. According to the announcement made in Minneapolis, a gift of \$150,000 has been received toward the salary of the professorship, which may be supplemented from the income of the Mayo Foundation for Medical Education and Research. Harold S. Diehl, M.D., the Dean of Medical Sciences, pointed out that this professorship is a significant milestone in the development of the University, assuring for the School of Public Health a permanent professorship beyond what the University otherwise could provide.

The University of Minnesota School of Public Health was established about two years ago as an outgrowth from the Department of Preventive Medicine and Public Health in the School of Medicine. Gaylord W. Anderson, M.D., Dr.P.H., has been Professor of Public Health and Director since its

establishment. The Mayo Properties Association was formed by the late Drs. Charles H. and William J. Mayo and their associates to hold and manage assets of the Mayo Clinic. The Mayo Foundation for Medical Education and Research is an educational division of the University of Minnesota on a graduate level. It was first endowed with \$2,000,000 in 1917, which sum was subsequently increased by \$500,000 in 1934.

ADVANCED STUDY FOR GRADUATE NURSES

In accordance with instructions of the President and Congress, Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, set October 15, 1945, as the final date on which federal funds would be available to graduate nurses for advanced study. Under terms of the Bolton Nurse Training Act of June, 1943, federal scholarships were provided for graduates, to increase the number of instructors and to prepare more nurses for such important specialized fields as public health and psychiatric nursing. As of October 15, 1945, approximately 15,000 graduate nurses had received federal aid for this purpose. Where these nurses could not be spared from their positions to take postgraduate preparation a series of on-the-job courses was brought to the hospital as an emergency measure to aid nurses who were pressed into positions for which they were not fully prepared. Of the 15,000, about 5,000 were enrolled in these intensive courses.

LEGION OF MERIT TO LT. COL. MCCOY

The U. S. Army has announced the award of the Legion of Merit to Lt. Col. Oliver R. McCoy, Director of the Tropical Disease Control Division, Preventive Medicine Service, Office of the Surgeon General, for fostering activity in the field of malaria treatment and control, in the dissemination of knowledge pertinent to tropical disease con-

trol in professional circles and among troops, thus maintaining their health while operating in overseas areas. His "outstanding achievements in bringing into being a means of production of quinine and related antimalarials signify a magnificent contribution to mankind."

PAN-AMERICAN CONGRESS OF PEDIATRICS

Announcement has been made by Dr. Felix Hurtado of Havana, Cuba, of the plans for the first Pan-American Congress of Pediatrics to be held in New York City in the fall of 1948. The Chairman of the Organization Committee is Dr. J. L. Durand of Seattle, Wash. Dr. Hurtado is Associate Chairman. Latin American members of the committee include:

Dr. F. Gomez, Mexico City, Mexico
 Dr. E. Soto, Pradere, Cuba
 Dr. C. Kruindick, Lima, Peru
 Dr. M. A. Barboza, Rio De Janeiro, Brazil
 Dr. C. Umana, Bogota, Colombia
 Dr. A. Scroggie, Santiago, Chile
 Dr. V. Escardo, Montevideo, Uruguay

According to Dr. Hurtado, the aims of the Congress will be:

1. Consideration of scientific and cultural affairs relating to the diagnosis and treatment of the diseases of children
2. A review of the methods of teaching pediatrics
3. Consideration of newer systems of medical practice in a changing society

MENTAL HYGIENE PROGRAM IN BERKELEY'S DEPARTMENT OF HEALTH

On an experimental basis the City of Berkeley, Calif. (population, 97,000), has recently developed a city mental hygiene program under the direction of Frank L. Kelly, M.D., Dr.P.H., the City Health Officer. With an initial budget of \$11,500, of which \$5,000 is a foundation grant, and \$4,500 from the State of California, the project will be undertaken for a year, at the end of which time a full report will be made on techniques developed, methods of

financing, and the part to be played by the citizens' advisory committee in the development of a program.

FLUORINE AND WATER SUPPLY

Extension of the fluorine studies under way in Newburgh and Kingston, N. Y., and in Grand Rapids, Mich., is indicated by a recent decision of Evanston, Ill., and Sheboygan, Wis., to add fluorine to the water supply. In Evanston coöperation between the city and state health departments and the University of Chicago dental clinic provides for a 15 year study to determine whether the addition of fluorine to water will protect teeth from decay. Mouth x-rays will be made of all children in the 6 to 8 and 12 to 14 year age groups.

In Sheboygan the Health Department, which is administering the program will make periodic reports to the city council.

SOUTH DAKOTA PUBLIC HEALTH ASSOCIATION

The South Dakota Public Health Association, the newest affiliated society of the A.P.H.A., held its Seventh Annual Meeting in Mitchell on December 14 and 15. At this meeting the following new officers were elected:

President—C. E. Sherwood, M.D., Madison
Vice-President—H. Russell Brown, M.D., Watertown
Secretary-Treasurer—Gilbert Cottam, M.D., Pierre

COURSE IN PUBLIC HEALTH PRACTICE FOR VETERANS

The George Washington University School of Medicine, Washington, D. C., has announced that two weeks of instruction in public health practice on a full-time basis will be offered to physicians beginning March 11. The first week will be devoted to the study of various infectious diseases, including problems of diagnosis and treatment and epidemiology. The second week

will be devoted to the study of facilities for public health practice at the National Institute of Health and in large city and county units. According to the announcement, all costs of the course are met for medical veterans by the provisions of the G.I. Bill of Rights. Inquiries should be directed to the Director of Postgraduate Instruction, George Washington University School of Medicine, 1335 H Street, N.W., Washington 5, D. C.

TYPHUS COMMISSION MEDAL TO CAPTAIN DAITZ

Captain Bernard D. Daitz, Sn.C., has been awarded the Typhus Commission Medal by the Surgeon General of the U. S. Army for "meritorious service in connection with the work of the United States of America Typhus Commission in Naples during the winter of 1943-1944." The citation reads in part: "Captain Daitz assisted in the organization and development of the system of recording all cases of typhus fever reported in Naples. This work included supervision of an office of records, development of a useful reporting form and provision of daily and weekly reports. In connection with the reporting system, he participated at times in the activities of the typhus case finding teams. His services were an important factor in assembling and making available information essential to the successful prosecution of measures for the control of typhus."

PUBLIC HEALTH SERVICE TO SURVEY CHICAGO

Dr. Frank V. Meriwether, Director, District of the U. S. Public Health Service, has announced a survey of the Chicago health facilities by his office. The study was requested by the Chicago Medical Society, the Institute of Medicine of Chicago, and the Health Division of the Chicago Council of Social Agencies, and will probably require a

year to complete. Brig. Gen. James Thompson will direct the project.

BRIGADIER GENERAL STANHOPE BAYNE-JONES AWARDED DISTINGUISHED SERVICE MEDAL

Brig. Gen. Stanhope Bayne-Jones, Deputy Chief of the Preventive Medicine Service, Office of The Surgeon General, has been awarded the Distinguished Service Medal for his outstanding "contribution to the maintenance of health within the Army."

"As Administrator of the Epidemiological Board," the citation stated, "he directed the extension, administration, and military application of the worldwide research and control program conducted by this board and its ten commissions."

Born in New Orleans, La., General Bayne-Jones is a graduate of Yale University and Johns Hopkins University Medical School. He entered the Medical Reserve Corps in 1915 and served throughout World War I. From 1917 to 1918 he served with the British Expeditionary Forces in France and Italy and later with the AEF in France and Germany, and has been decorated with the British Military Cross, the French Croix de Guerre, and the Silver Star with Two Oak Leaf Clusters.

Prior to being ordered to active duty in 1942, General Bayne-Jones was Professor of Bacteriology at Yale University and had held the position of Dean of the School of Medicine at that University.

U. S. PUBLIC HEALTH SERVICE NEEDS PHYSICIANS, DENTISTS AND NURSES

Appointments to fill vacancies in the Reserve Corps of the U. S. Public Health Service are now being made, and examinations for Regular Corps appointments will be held in April and May. Physicians, dentists, and nurses are needed immediately for duty in hospitals, in the Tuberculosis and

Venereal Disease Control programs, and in other activities of the Public Health Service.

Pay and allowances, established by law, are identical with those for medical officers of the Army. All travel expenses, including travel to first station, are paid by the Service.

Appointments to the Reserve Corps are made on a basis of review of data furnished by the applicant. Physical examination is required. Regular Corps appointments require appearance before a Board, and a written professional examination. A person receiving an appointment in the Reserve Corps immediately, may, if he desires, take the examinations for the Regular Corps at the time they are held.

Those interested in either immediate appointment in the Reserve Corps, or in taking the examination for the Regular Corps, should request application forms of the Surgeon General, U. S. Public Health Service, Washington, D. C.

FLORIDA PUBLIC HEALTH ASSOCIATION

At a recent meeting, the following new officers were elected:

President—George A. Dame, M.D., Jacksonville

First Vice-President—Homer D. Venters, Tampa

Second Vice-President—Ruth E. Mettinger, Jacksonville

Secretary-Treasurer—Edward M. L'Engle, M.D., Jacksonville

The following four sections were officially organized and recognized:

Sanitation Section

Health Officers' Section

Public Health Nursing Section

Clerical Section

THE CHURCH AND THE HEALTH OF THE COMMUNITY

Last October a number of Harlem health agencies and churches, recognizing the close interrelation of their separate interests, sponsored a three week "Health Institute for Ministers."

Thirty ministers attended the Institute and at a special ceremony received certificates in recognition of their interest in better health from Dr. Ernest L. Stebbins, Health Commissioner of New York City.

NEW YORK TUBERCULOSIS AND HEALTH ASSOCIATION

The 14th Annual Conference of the New York Tuberculosis and Health Association will be held March 21 at the Hotel Pennsylvania.

Sessions on various phases of community health and welfare will be conducted throughout the one day meeting.

Election of officers of the Tuberculosis Sanatorium Conference of Metropolitan New York, which will meet simultaneously, also will be held.

TERRITORY OF HAWAII ADOPTS COMMUNICABLE DISEASE REPORT AS OFFICIAL

C. L. Wilbar, Jr., M.D., President of the Board of Health of the Territory of Hawaii, Honolulu, has announced that the Board of Health of the Territory has adopted as official for Hawaii the report on the *Control of Communicable Diseases*, published by the American Public Health Association.

"SOCIAL STATISTICS" COMES HOME

Two decades ago, in 1924, Raymond Clapp of the Cleveland Welfare Federation, in coöperation with the National Community Chests and Councils, undertook a study of the expenditures and services in the local community councils of 19 cities. At the beginning of 1946 the National Community Chests and Councils became responsible for national direction of the Social Statistics Project hitherto sponsored by the U. S. Children's Bureau. Thus a project begun by a private agency as a demonstration and later turned over to and matured in a public agency because

of its greater resources and stability, has now been turned back to the private agency that first gave it birth.

The history of the undertaking is briefly: In 1927, after Mr. Clapp's 1924 study, Community Chests and Councils and the Community Research Committee of the University of Chicago organized a joint committee to plan for the collection of monthly reports from social agencies. By 1929, reports were received from 25 urban areas in 16 states, and the data were analyzed in a volume called "Registration of Social Statistics."

In 1930 the project was turned over to the Children's Bureau, coöperation continuing from Community Chests and Councils and other national agencies, chief among them the Russell Sage Foundation. In the 16 years of the bureau's sponsorship the project was expanded greatly. Between 1933 and 1937, 20 issues of the *Social Statistics Bulletin* were published, including figures on a wide range of social services.

Beginning in 1937, Social Statistics became a supplement to the Children's Bureau monthly, *The Child*. It has published statistics on hospital and outpatient services, on public health nursing, juvenile court and juvenile delinquency statistics, employment certificate statistics, data on day nursery and foster care, periodical reviews of relief statistics, figures on care of crippled children, neglected and delinquent children, group work statistics, maternity home care and maternity homes, statistics on homes for aged, chronically ill and dependent adults, transient service statistics, data on sources of funds for health and welfare programs, and finally an analysis of services of state health departments to mothers and children.

The Community Chests and Councils is again fathering this project. It will be supervised by a national advisory committee made up chiefly of local

community council executives but including also statisticians, among them Ralph Hurlin of the Russell Sage Foundation and Anne Geddes of the Federal Security Agency, who were active in the early days of the project, and Edward Schwartz who supervised the project in the Children's Bureau. Three members of the A.P.H.A. are on the Committee: Professor Ira V. Hiscock, Bertram Black, the Chairman of the committee, and Sara Kerr, Executive Secretary of the Buffalo Foundation. The director of the 1924 study, Raymond Clapp, and the Editor of *Survey Mid-Monthly*, Bradley Buell, are also committee members.

In addition to a central staff, present plans are for regional representatives on a part-time basis for field service and regional promotion. Regional workshops are also planned for the coming summer. Review of the report forms is now under way and some revisions may be made for the reporting year 1947. Currently 44 urban areas have participated in the project over a period of time.

BARUCH COMMITTEE ON PHYSICAL MEDICINE

Bernard M. Baruch in 1944 made an initial grant of \$1,100,000 to the Baruch Committee on Physical Medicine, to advance and encourage research, teaching, and training in the field of physical medicine—and to bring the benefits of this branch of medicine to the rehabilitation of persons maimed in war, industry, or by illness. The first annual report of the committee, prepared by the medical director, Frank H. Krusen, M.D., of the Mayo Clinic, has outlined the progress in attaining the objectives of Mr. Baruch's endowment. Eleven medical schools share funds in the original grants: Columbia University, \$400,000; New York University, \$250,000; Medical College of Virginia, \$250,000; Massachusetts Institute of

Technology, \$50,000; University of Minnesota, \$40,000; University of Southern California, \$30,000; Harvard University, \$25,000; University of Iowa, \$15,000; University of Illinois, \$15,000; Washington University, \$10,000; Marquette University, \$5,000; Harvard received a later special grant of \$30,000 for a special fellowship program.

APPOINTMENTS TO NATIONAL ADVISORY CANCER COUNCIL

Appointment of Dr. Robert S. Stone, Professor of Roentgenology at the University of California, and Dr. Charles B. Huggins, Professor of Surgery at the University of Chicago School of Medicine, for three year terms on the National Advisory Cancer Council has been announced by Surgeon General Thomas Parran of the U. S. Public Health Service, Federal Security Agency.

The new Council members replace Dr. Baird Hastings of Harvard University and Dr. James B. Murphy of the Rockefeller Institute, whose terms have expired.

The National Advisory Cancer Council is composed of six members in addition to the Surgeon General of the Public Health Service, who is chairman, ex officio. It serves as an advisory body to the Surgeon General in the direction of the work of the National Cancer Institute.

PERSONALS

Central States

ANTHONY J. BOROWSKI, DR.P.H.,* was appointed Registrar and Superintendent of the Bureau of Vital Statistics of the Department of Health, City of Toledo, Ohio, on November 15.

HARRY E. CARNES, M.D.,† has been discharged from the Army and has rejoined the staff of Parke, Davis &

Company, in the Division of Biological Production, Detroit, Mich.

CARL W. HAMMER, M.D., Oxford, Mich., has been named Assistant Professor of Health Education at the Montana State College, Bozeman, and Director of the Student Health Clinic.

PERCY L. HARRIS, M.D.,† Ravena, O., Health Commissioner of Portage County since 1938, has been appointed Chief of the Division of Communicable Diseases of the Ohio State Department of Health.

CHANGES IN HEALTH PERSONNEL IN ILLINOIS:

IRENE FAHEY, M.P.H.,† was employed as Health Educator by the Cook County Department of Health, effective November 1.

GERTRUDE KOENEMAN, R.N.,† has resigned from District 18, Illinois Department of Public Health, to enroll in the University of Minnesota for further graduate work. She will be replaced by THERESA KERN, R.N., former Supervising Nurse, Williamson County Health Department.

CAPTAIN CALVIN COREY † resumed his duties as Bacteriologist with the Illinois Department of Public Health, Springfield, effective October 16.

CAPTAIN GEORGE K. HENDRIX † resumed his duties as Sanitary Engineer with the Illinois Department of Public Health, Springfield, effective October 16.

MAJOR HERBERT E. McDANIELS * resumed his duties as Bacteriologist with the Illinois Department of Public Health, effective December 1.

MELVIN T. JOHNSON, M.D.,† has been named Medical Director of Iowa

Public Health District Number 5, Fort Dodge, Ia., succeeding FORREST J. AUSTIN, M.D.,† now of Omaha, resigned.

RUSSELL E. PLEUNE, M.D., Hancock, Mich., formerly Director of the Houghton-Keweenaw-Baraga Health Department and recently released from the Army, has been appointed Deputy Commissioner of Health of the upper peninsula with offices in Escanaba, with the State Board of Health, succeeding WILBER J. M. MENKE, M.D.†

ELDRED V. THIEHOFF, M.D.,* has been appointed City Health Commissioner of Peoria, Ill., to succeed the late SUMNER M. MILLER, M.D.,* effective January 7, 1946. Dr. Thiehoff has been associated with the Michigan Dept. of Health since 1940, for one year as Assistant Director of the Bureau of Local Health Services, and since as Director of the same Bureau. In addition, he was Deputy State Health Commissioner for 3 years.

Eastern States

BURTIS B. BREESE, JR., M.D., Rochester, N. Y., has been named Deputy Health Officer of the Rochester Health Bureau, effective January 1. Dr. Breese is the first of two new officers to be appointed to positions in the Health Bureau. He will be concerned chiefly with communicable diseases. A second health officer, who will specialize in venereal diseases, will be appointed later.

MRS. HELEN R. COOLEY of the staff of the State Committee on Tuberculosis and Public Health, State Charities Aid Association, New York City, has been appointed Executive Secretary of the Tompkins County Tuberculosis and Public Health Association at Ithaca, N. Y., succeeding LOUISE BARCOCK, who has resigned to accept a position in California.

* Fellow APHA
† Member APHA.

EDITH M. GATES,* formerly in charge of health education with the National Board, Y.W.C.A., New York City, has recently been in Cyprus on the staff of UNRRA and concerned with the repatriation of displaced persons. More recently she has been working in vocational rehabilitation of refugees in Switzerland as the representative of the American Christian Committee for Refugees.

HELEN S. MITCHELL, Ph.D.,* of New Haven, Conn., was appointed Professor of Nutrition, Department of Home Economics at the Carnegie Institute of Technology, Pittsburgh, Pa., effective January 28.

CHANGES IN HEALTH OFFICERS IN NEW YORK STATE:

JOHN A. CONWAY, M.D.,* dean of New York District State Health Officers, retired January 1 after 31 years' service in the State Department of Health. For many years, he has served the counties of Allegany, Chemung, and Steuben from headquarters in Hornell.

DANIEL P. McMAHON, M.D.,† formerly District State Health Officer in Amsterdam, N. Y., has returned from military service. He will serve as District State Health Officer in the Hornell district.

ALEXANDER ZEISSIG, D.V.M., Ph.D., has been appointed Veterinary Consultant on rabies on the staff of the Division of Communicable Diseases.

WALTER M. PAMPHILON, M.D., Willard, N. Y., Assistant Director of the Willard State Hospital, has been named Assistant Commissioner of the New York State Department of Mental Hygiene. Dr. Pamphilon, who had previously been detailed as Acting Medical Inspector, has been

assigned to the Inspection Service of the Department and will be on duty in the New York City office for part time, besides assisting with the Department's program for post-war building.

JOHN B. PASTORE, M.D., has been appointed Executive Director of the Hospital Council of Greater New York. He formerly was Assistant Director of New York Hospital where he had considerable experience in general administration and the development of special programs. Dr. Pastore has participated in several projects at New York Hospital and Cornell Medical College and has taken an active interest in hospital problems in the community. He will direct the planning and coordinating programs of the hospital council.

WILLOUGHBY J. ROTHROCK, JR., M.D., Philadelphia, Pa., has been assigned by the U. S. Public Health Service as Director of the Tuberculosis Control Program for the Chattanooga-Hamilton County Health Department, Tennessee.

WILSON G. SMILLIE, M.D.,* Professor of Public Health at the Cornell University School of Medicine and Member of the Association's Committee on Professional Education, is Chairman of the newly created Public Health Committee of the New York County Medical Society.

EDWIN F. VOIGT,* Managing Director of the Biological Division of Wyeth, Inc., Philadelphia, expects to leave their employ shortly. Prior to working with Wyeth, he was for 20 years associated with Lederle Laboratories, Inc., at Pearl River, N. Y., as Bacteriologist, Assistant Director, and Director of the Biological Division.

Southern States

ASB BARNES, M.D.,† Jefferson City, Mo., has joined the staff of the Office

* Fellow A P H A
† Member A P H A

of the Medical Director, American Red Cross, in charge of general medical services. After more than 4 years' service in the Army Medical Corps, Dr. Barnes was recently discharged with the rank of colonel. He served 22 months in North Africa, Sicily and Italy.

BRIGADIER GENERAL RAYMOND W. BLISS has been appointed Deputy Surgeon General to succeed MAJOR GENERAL GEORGE F. LULL,† retired. In addition to his new responsibilities, General Bliss will continue to handle the duties of Assistant Surgeon General and Chief of Operations Service. His outstanding contributions to the achievements of the Medical Department in these capacities won him the Distinguished Service Medal.

MARJORIE GOOCH, Sc.D.,* has transferred from the Children's Bureau of the Dept. of Labor to The Division of Research and Statistics of the Social Security Board in Washington, D. C.

MAJOR CLIFFORD H. GREVE † has been released from the Army to inactive duty after four years of service. During this time, he served as Chief of the Statistical Division, Michigan State Headquarters for Selective Service and as Chief of the Medical Statistics Section of National Headquarters of the Selective Service System. Mr. Greve has assumed a position as Senior Statistician in the Bureau of States Services of the U. S. Public Health Service at Bethesda, Md.

LAWRENCE KOLB, M.D., Washington, D. C., formerly Chief of the Mental Hygiene Division of the U. S. Public Health Service, has been appointed Deputy Medical Director of the State Department of Mental Hygiene in California. This post, the first of its kind in California, was created by the 1945 legislature.

CHANGES IN HEALTH OFFICERS IN NORTH CAROLINA:

HAROLD C. WHIMS, M.D.,† Newton, Health Officer for Catawba County, has resigned to become Health Officer of Buncombe County, with headquarters in Asheville.

ZACK P. MITCHELL, M.D.,† Shelby, Health Officer of Cleveland County, has been named Health Officer of Iredell County.

LT. COL. JOHN W. REGAN, M.C., U.S.A.,† who has been Assistant Director of the Sanitation and Sanitary Engineering Division, Preventive Medicine Service, Office of the Surgeon General, Washington, has been appointed Director of that Division. Colonel Regan is a graduate of the Harvard Medical School in 1936.

ROY J. SETTLE, M.D.,† recently discharged from the Army Medical Corps, has been appointed Director of the Williamson County Health Department, Tennessee, succeeding WILLIAM B. FARRIS, M.D.†

THEODORE R. SHROP, M.D.,† following his release from active duty with the U. S. Public Health Service, is now serving as Deputy State Health Officer of the Maryland State Department of Health, assigned as Health Officer of Howard County, with offices at Ellicott City, Md.

WINFORD H. SMITH, M.D., for 34 years Director of the Johns Hopkins Hospital, will retire March 31. His successor will be EDWIN L. CROSBY, M.D.,* Assistant Director since 1940. Dr. Smith was President of the American Hospital Association in 1916 and the first President of the Maryland-District of Columbia Hospital Association of 1941. Before coming to Johns Hopkins, Dr. Crosby was associated with the New York State Health Department.

* Fellow A.P.H.A.

† Member A.P.H.A.

ELSBETH H. VAUGHAN, R.N.,* Washington, D. C., recently resigned from the Red Cross Nursing Services. Having resigned as Director of Public Health Nursing and Disaster Nursing in 1937, Mrs. Vaughan returned to the Red Cross in 1940, and became Director of Nursing in the Midwestern Area. In 1935 Mrs. Vaughan was awarded the Florence Nightingale medal.

CHANGES IN HEALTH OFFICERS IN VIRGINIA:

WILLARD W. GRIGGS, M.D., Newport News, has been named Health Officer of the Page-Warren-Shenandoah Health District, effective November 1.

JAMES M. SUTER, M.D.,* Bristol, has returned to service with the Virginia Department of Health as Health Officer of the Smyth-Washington-Bristol Health District, effective December 6.

FREDERICK C. HEATH, M.D., Laureldale, Pa., has been appointed Health Officer of the Giles-Montgomery-Radford Health District, with headquarters at Christiansburg, effective January 1.

Western States

HARRY V. GIBSON, M.D.,† Health Officer for a number of years of Great Falls, Mont., has been placed in charge of the reorganized Health Department in Great Falls and Cascade County.

GEORGE HILL HODEL, M.D.,* of Los Angeles, Calif., is en route to China on a public health mission for UNRRA, in the capacity of Chief Regional Medical Officer. Dr. Hodel is Chief of Staff of the First Street Clinic, Los Angeles, and was for several years Chief of the Division of

Social Hygiene in the Los Angeles County Health Department. His assignment to UNRRA is expected to last until the spring of 1947.

MARTIN KARR, M.D., San Mateo, Calif., has been employed as Medical Officer in the State Bureau of Maternal and Child Health and assigned to the Bureau of Vocational Rehabilitation, State Department of Education, where he will give assistance in developing the new physical restoration program of that agency along the lines of the medical care programs of the Department of Public Health.

DOUGLAS G. MACPHERSON, M.D., San Francisco, Calif., formerly Director of the Los Angeles City Division of Industrial Hygiene, is now Chief of the Los Angeles County Division of Industrial Hygiene, replacing HUGH E. DIERKER, JR., M.D.,† who has become Medical Director of the Southern California Division of the General Motors Corporation.

THOMAS F. MANCUSO, M.D., Acting Director of the Division in Industrial Hygiene, Oregon State Board of Health, Portland, has been appointed Chief of the Division of Industrial Hygiene of the Ohio Department of Health.

A. V. NASATIR, M.D.,* has returned from nearly four years of military service to his former position as Director of the Division of Industrial Hygiene, City of Los Angeles Department of Health. Dr. Nasatir served in an industrial medical capacity in this country and went through the European invasion with the First Army during which he was assistant G-5 of the First Army, Chief of the Public Health Section.

GEORGE F. O'BRIEN, M.D., Sacramento, Calif., has been appointed Health Officer of Stanislaus County to succeed J. LYLE SPELMAN, M.D.,† of Cenese, resigned.

* Fellow A.P.H.A.

Opportunities for International Health Activities

HUGH R. LEAVELL, M.D., DR.P.H., F.A.P.H.A.*

Rockefeller Foundation, New York, N. Y.

TODAY'S opportunities for effective international coöperative organization and administration in the health field are greater than ever before. Enormous problems cry out for solution. And at the same time the United Nations Organization is being set up, a great new venture with machinery designed realistically to attack world problems. Experience of the past is available to serve as a guide for future operations, so that previous mistakes may be avoided, and yesterday's considerable record of successful joint activities extended. There is less occasion for controversy in the health field than in almost any other.

This really unique situation demands aggressive action and the highest quality of leadership, much of which must come from America just now. Our resources in trained health personnel are greater than at any previous period in our history. During the war our losses and suffering have been less

severe than experienced by many other nations. Should we fail to grasp this opportunity and accept our responsibility we will probably never again have a chance equally good.

The world has new difficulties demanding attention in addition to the old health problems of communicable disease, malnutrition, inadequate housing and a host of others. The great speed of modern transport and communication and the destructiveness of modern warfare, atomic and otherwise, have created opportunities beyond our previous dreams. Whether or not he likes the idea, the health of a man's neighbors concerns everyone on this planet. Even with better technical knowledge and more effective tools at hand than ever before our health defenses can be only partially effective unless built on a firm international or supra-national framework.

Past and present experience can serve as useful guides for action. The Health Section was unquestionably one activity of the League of Nations which made most important contributions to world welfare and happiness. There is enormous value in the communicable dis-

* Recently on active duty as Senior Surgeon (R), U.S.P.H.S., assigned as Deputy Director, Health Division, United Nations Relief and Rehabilitation Administration, European Regional Office, London, England.

ease intelligence services and other functions carried on by the Pan American Sanitary Bureau and by the Office Internationale d'Hygiene Publique in Paris. In UNRRA the Health Division has the responsibility of administering the International Sanitary Conventions of 1944 as well as other duties related to relief and rehabilitation of war-torn territories and populations of the United Nations. These agencies already carry on tasks recognized as essential, and have personnel with rich experience arising from their work as international civil servants. In addition a number of philanthropic organizations have acquired a very useful body of information from widespread and productive international health projects.

Thus there are a number of people equipped to advise on the pitfalls to be avoided as well as the most profitable fields for future development in international health organization and action. It remains to be seen how these available assets can be used most effectively in setting up the health section which is to be a part of the United Nations Organization. Many competent persons are carefully weighing the situation and we may confidently expect definite proposals in the very near future.

Naturally, only a few will be called on to make the weighty decisions required. What can other health workers in America do to help solve these questions which so vitally affect us?

We have numerous opportunities if we are willing to seek them out and grasp them as they arise. One profitable approach lies in the cultivation of better understanding of other nations, their problems and their people. This may come from study of needs existing elsewhere and the resources and organization available to meet them. In addition, many of us will be in personal contact with "foreign" health workers coming to America as students, fellows

or observers. They will seem less foreign if we take the initiative and get to know them more than superficially. Undoubtedly we shall discover that our visitors can make real and valuable contributions to American health practice in return for what we do in facilitating their observation of our methods. A smaller, more fortunate group of us will be able to visit other countries. This will be the best method of gaining understanding, provided we travel as the learners which all good teachers must be.

In discussions among ourselves it is apparent that often we are none too certain of the value of some of our health practices. Perhaps distance lends enchantment to them when we expect other peoples to adopt American ideas more or less at a single gulp without stopping for breath. And this even though conditions may be vastly different from ours in the country concerned and the health movement in quite another phase of development.

A good many of us associated with UNRRA were almost incredulous when it became evident that some of the devastated countries, while quite ready to accept needed medical supplies, were very hesitant to accept suggestions for the improvement of their admittedly inadequate health services. Some of us had failed to recall how long it has taken us to reach our present level of attainment. We had neglected also to ask ourselves how willingly we in America would have accepted advice from "foreigners" even though they came to us bearing much needed gifts. Perhaps it was quite natural for health authorities of the countries being assisted to wonder how we could expect to gain an authoritative knowledge of their needs within only a few weeks or months of residence.

If approached philosophically and if we avoid annoyance at what may appear rebuffs, this UNRRA experience

can be extremely useful. Thoughtful consideration may show where mistakes have been made and where expectation has greatly exceeded the probability of success, at least within a relatively short period of time.

Those who have been in Europe recently find upon returning to America what seems a strange indifference to world problems. This may be a sort of war weariness, but even if that is the explanation America has much less reason to be war weary than most other nations. We have had to give up comparatively little in the way of comforts. Our food supply has been more than adequate, and war damage of our buildings restricted to that resulting from the crash of one of our own planes into the Empire State Building. We are surely in physical condition for world leadership provided our moral fiber is sufficiently strong.

My own experience in Europe was limited to a year, mostly in England, but also in Germany, France, and Belgium. Destruction of buildings is greater in Germany than elsewhere and undoubtedly the German people are having an extremely tough winter

with many deaths probable. Malnutrition and exposure have reduced resistance to communicable disease to the point where case fatality rates are three or four times the normal. The British people are tired after several years of suffering, but their spirit has been remarkably good throughout. British public health practice is sufficiently similar to ours for us to have no serious difficulty in working closely together on common problems, and there is much that we can learn from them. Close collaboration between British and American military forces is recognized as an outstanding product of this war. There is every reason to believe that it may be successfully continued to strengthen the peace. And in the health field the prospect is particularly bright.

Even with a limited experience, my convictions of the need for present international health coöperation are very strong. Those who have seen conditions abroad have a real responsibility to point out to their coworkers the possibilities inherent in the present situation. This appeal is made in that spirit.

The Norton Medical Award

Announcement has recently been made of the third annual Norton Medical Award of \$3,500. This award of the publishing firm W. W. Norton & Company is offered to encourage the writing of books for laymen by medical men or books which relate medicine to society and demonstrate the spirit that inspires and sustains men of medicine in their work. The final date for delivery of manuscripts is November 1, 1946, and the award will be announced and the manuscript published early in

1947. Full details may be secured from W. W. Norton Company, 70 Fifth Avenue, New York 11.

The first of these awards was made to Dr. Carl Binger in 1945 for *The Doctor's Job*. The winning book for 1946, announced in March for May publication, is *Doctors East, Doctors West! An American Physician's Life in China*, by Dr. Edward H. Hume. Dr. Hume spent nearly twenty-five years in the Yale Medical College in China of which he was a founder and organizer.

Bacteriologic Procedures in the Evaluation of Methods for Control of Air-borne Infection

WILLIAM F. WELLS, F.A.P.H.A., C.-E. A. WINSLOW, DR.P.H.,
F.A.P.H.A., AND ELIZABETH C. ROBERTSON, M.D., PH.D.

*School of Medicine, University of Pennsylvania, Philadelphia; New Haven, Conn.;
and Department of Pediatrics, University of Toronto*

MICROÖRGANISMS ordinarily invade the atmosphere on dust particles, in droplets, or in the nuclei of instantaneously evaporated droplets, normally differentiated as follows:

The differentiation by bacteriologic procedure of each of these three classes of air-borne infection has profoundly changed our concepts of disease transmission. Thus the demonstration, a

	Dust	Droplets	Droplet Nuclei
SOURCES OF MATERIAL	Solid matter; fabrics, etc.	Fluids from nose and throat	Solid residues of evaporated droplets
PRODUCTION	Attrition	Atomization of fluids	Evaporation of droplets
MODE OF SUSPENSION	Air wafted	Projected into air by sneezing, etc.	Caught in air by evaporation
PARTICLE DIAMETER	10 to 100 microns	Larger than 100 microns	2 to 10 microns
SETTLING VELOCITY	Foot per minute to foot per second	Greater than foot per second	Less than foot per minute
TIME OF SUSPENSION	Limited by settling velocity	Less than 3 seconds	Limited indoors by ventilation
FLIGHT RANGE	Hovers in clouds	Immediate in space	Dispersed throughout indoor atmosphere
CONCENTRATION	Locally high	Immediately intense	Diffuse and dilute
AGE OF INFECTION	Survivors of accumulation	Fresh	Limited by ventilation
TYPES OF ORGANISMS	Mostly saprophytic	Parasitic and pathogenic	Parasitic and pathogenic
NUMBER PER CU. FT.	Normally below 100	Indeterminate	Normally below one
BACTERIA/PARTICLE	Clumps	Indeterminate	Seldom more than one
INHALATION	Trapped in nose and throat	Indeterminate	Penetrate to lung

	<i>Dust</i>	<i>Droplets</i>	<i>Droplet Nuclei</i>
MODE OF INFECTION	Endemic infection of nose and throat	Contact infection	Epidemic contagion
PATTERN OF INFECTION	Static	Indeterminate	Dynamic
VULNERABILITY	Resistant	Indeterminate	Vulnerable to chemical and physical agents
REMOVAL	Filtration and electrostatic precipitation	Best by face mask	Electrostatic precipitation; difficult by filtration
CONTROL	Air cleanliness	"spacing out"	Sanitary Ventilation (air change and equivalent air disinfection)

century ago, that boiled fluids might not spoil if protected from floating germs led to the science of bacteriology and the germ theory of disease. Air-borne germs seemed to offer a rationalization of the generally accepted miasmatic theory, and the study of air-borne organisms dominated the early development of bacteriology. But dust-borne bacteria were found to be mostly saprophytic; pathogenic organisms causing intestinal disease were found mostly to be ingested; and the most typical miasm of all—malaria—was found at last to be insect-borne. The validity of these newer concepts was abundantly confirmed by the success of sanitary control based on analytical procedures.

But respiratory infections, caught from persons sharing indoor atmospheres—i.e., contagious diseases—did not yield to sanitary control; for, almost fifty years ago, bacteriologists had concluded that these infections also were not air-borne, because droplets coughed or sneezed into the air did not settle upon Petri plates exposed beyond a few feet. Our generation, taught that contagious disease was transferred by immediate contact—for proximity in time and space required to infect by such droplets was construed as a form of contact—paid little heed to sanitary ventilation.

This fallacy was however refuted, a decade ago, by recovery of virulent or-

ganisms in the residues of instantaneously evaporating droplets; these nuclei settled so slowly that they had been missed on exposed Petri plates. If the nuclei of infected droplets, coughed or sneezed into the air, drift like cigarette smoke on air currents until breathed, vented by air replacement, or removed by purification processes, then sanitary control of ventilation must be guided by bacteriological procedures capable of distinguishing these droplet nuclei.

BACTERIOLOGIC PROCEDURES

Procedures developed in half a century of intensive study of dust-borne bacteria and droplet infection were reviewed by the Committee on Standard Methods for the Examination of Air (1917); adequate methods adopted by the Association are still in force: the exposed plate gave the number of bacteria-bearing particles; the filter or washer gave the number of dust-borne bacteria. But dust-borne organisms had already been acquitted by bacteriology; between the acceptance of the final report in 1917 and the description of a new apparatus for study of the bacterial behavior of air in 1933, practically no contributions to this subject appeared in the *American Journal of Public Health*.

Experimental procedures introduced by the new sampling method aroused

immediate interest in air-borne infection and disinfection of air, which led in 1936 to the creation of a subcommittee with the special task of recommending procedures capable of differentiating droplet nuclei infection from dust- or droplet-borne infection. Six progress reports have been submitted (1937-1942) and these were integrated into a consistent system of sanitary air analysis (Wells, 1943). The creation of another subcommittee for evaluating methods of control of air-borne infection indicates the need of routine bacteriological procedures in specifying sanitary ventilation.

Droplet nuclei are characterized by small size of particle—small weight compared to surface area. Air friction clutches the surface of small particles in accordance with Stokes' Law of Viscosity, the essential quality which makes air a vehicle of infection. Except for air viscosity, particles would quickly sediment in accordance with Newton's Law of Gravity. Settling velocity which, according to Stokes' Law, varies with the surface area or the square of particle diameter, governs suspension or flight range of particles; measures air drag which sweeps them into the respiratory tract; and is often correlated with sources of infection. Settling velocity thus becomes the most significant physical determination of air-borne infection relative to pollution and purification of air.

The settling velocity of nuclei of culture broth, atomized into a quiet chamber 8 ft. on a side, has been exhaustively studied by Phelps. Simultaneous plate exposures at different points (Phelps and Buchbinder, 1941) showed uniform density throughout the chamber, enabling computation of settling velocity from successive plate exposures. Bacteria-bearing nuclei, according to these computations, settled 0.03 ft. per min.—the value plotted on Chart 1. Few droplet nuclei would

therefore be deposited in ventilated rooms. So slowly do they settle that their concentration in ventilated atmospheres is determined by rate of addition divided by ventilation rate, rather than upon room activities. As they do not accumulate on surfaces, the dispersion of infected droplet nuclei depends upon the presence within the atmosphere of a person in an infective stage—a characteristic of contagious disease recognized since early times.

Dust deposit depends upon settling velocity; in fact, the ratio of area count (rate of deposit) to volume count (number of bacteria-bearing particles rather than bacteria borne by the particles) defines settling velocity of particles. Values of mean settling velocity of bacteria-bearing particles in various atmospheres as determined by this simple procedure, are tabulated and plotted on Chart 1. Obviously most dust particles settle faster than 1 ft. per min. in ordinary atmospheres. Under conditions of exceptional activity, capable of retaining coarser matter in the air, the average value is greater; under quiet conditions, or where droplet nuclei have been added to the atmosphere (e), the average value may be less. In any case, accumulated dust can be stirred up by activities independent of the presence of an infective person. Resistant organisms in such accumulations, if not removed, are a continual threat of static air-borne infections in contrast to dynamic nuclei contagion. Dust particles, unlike droplet nuclei which readily penetrate to the lung, are more associated with endemic infections of the nose and throat than epidemic phenomena of contagion.

It follows, from the small size of atomized droplets, that seldom would more than one organism be included in a nucleus; this distinguishes droplet nuclei from dust-borne clumps of bacteria. Individual organisms in dust particles, collected in liquids, as by the accepted methods of the Association,

CHART 1. SETTLING VELOCITY of Air-borne Infection, $V_g = A/D$, where A = rate of deposit and D = density. AREA COUNT = rate of deposit per sq. ft. per min. (15 min. exposure of Petri dish). VOLUME COUNT = air centrifuge count per cu. ft. per density of 100 bacteria-bearing particles per cu. ft. VOLUME COUNT/AREA COUNT is multiplied by ten.

are separated and counted as colonies; whereas a droplet nucleus would probably register merely as a single colony. Thus a large number of bacteria per particle, or total bacteria count divided by the count of bacteria-laden particles, may be a useful index of dustiness rather than infectiousness of air.

These procedures merely characterize dust in routine analysis, for droplet nuclei seldom carry more than a negligible fraction of the total number of air-borne bacteria. Their genesis in the respiratory system, however, gives hygienic significance out of all proportion to their number, and necessitates means for distinguishing them from dust. Generally they contain organisms typical of the nasopharynx—lactose fermenting, Gram-positive, hemolytic streptococci. These organisms grow well on blood agar; but dilution methods analogous to those used for isolation of coliform organisms in drinking water are more sensitive. Air-borne organisms, collected in liquids, are distributed into enrichment broth tubes exactly as in testing drinking water, the presence of acid rather than gas in lactose being presumptive evidence of pollution. Hemolytic organisms are confirmed on blood agar containing enough gentian violet to inhibit staphylococci. The method of enumeration is similar to that applied in water analysis.

The growing recognition of air-borne infection as a basis for a theory of contagion has revived interest in sanitary ventilation. Just as bacteriologic procedures guided the development of water purification practice, so will they evaluate air disinfection processes. The rate of disposal of droplet nuclei infection can be measured by sampling standard suspensions of organisms atomized into air at a constant rate. Ventilation rates are proportional to the equilibrium concentrations, one dieaway rate being determined by successive samplings.

Compared to the amount of pure air replacement required to effect equal removal of the organisms, results express disinfection in terms of equivalent ventilation. To estimate disinfection against pathogenic organisms, relative vulnerability is determined in the laboratory against the standard organism.

Interpretation of the data is also subject to statistical limitations: Single determinations have little significance; fluctuations in occupation load in ventilation are greater than in pollution of drinking water. The hygienic quality of air, as in water, is an abstraction derived from a statistical analysis of a large number of samples obtainable only with a practical routine.

SAMPLING

It is generally conceded that, "There is no simple method that is optimal for all circumstances and species, and some degree of compromise is necessary." For our purpose, an air sampler must be capable of concentrating small numbers of nuclei from large volumes of air (a person breathes several cubic feet of air per hour) upon solid culture media or in small volumes of liquid. Phelps, in a careful analysis of the mechanism of deposition in the centrifuge, "operating between 4,000 and 5,000 r.p.m. with an air flow of approximately 1.4 to 1.9 cu. ft. per min.," recovered approximately one-third of the nuclei settling "approximately 22 inches per hour." Substituting this value of centrifuge performance in his equation, or a formula simplified by assumption of turbulent flow (Wells, 1943), gives for rated flow of 1 cu. ft. per min. and density of 100 particles per cu. ft. the "Volume Count" shown on Chart 1. Approximately one-half of these smaller nuclei and practically all particles settling more than 2 in. a minute (probably more representative of nuclei coughed or sneezed into the

atmosphere) would be collected according to this formula.

Complete collection of the smallest bacteria-bearing nuclei, rarely required, can be accomplished by reducing the flow of air or increasing the speed of the centrifuge. The rated flow is a practical compromise between complete recovery of the smallest laboratory nuclei capable of bearing a bacterial cell and the distributed collection of dust-borne bacteria on solid media satisfactory for counting. The settling velocity of droplet nuclei encountered in ventilation practice lies between these values, and their recovery by the centrifuge is practically complete.

A careful study of impingement methods developed for collection of fine industrial dusts (Bourdillon, Lidwell, and Thomas, 1941) has established the necessary velocity of particles of bacterial dimensions (through slits at optimal distances from the agar surface) to be 334 ft. per min.; sampling efficiency falls rapidly at lower velocities—dropping to one-fifth as the velocity falls to one-fourth. The slit sampler, satisfying these conditions, recovered from three to five hundred times as many fine broth spray nuclei from 10 cu. ft. of air as settled on a Petri plate in 10 minutes. The authors conclude, "This range of over 200 to 1 on the slit Petri ratio is very striking proof of the selective action of open dishes when used for collecting bacteria. It is probably safe to say that such dishes are at least 200 times as effective for collecting large bacteria-carrying particles as for single washed air-borne bacteria."

All samplers except the centrifuge require auxiliary equipment to draw measured quantities of air through the instrument. Convenience is important in collecting large numbers of samples, and the convenience of the centrifuge—creating its own measured air flow and depositing both dust and droplet nuclei

directly on solid or in fluid media—recommends it for field use. To obtain uniform results it is necessary to standardize on some method, even if it be acknowledged that no method can be most satisfactory for every purpose. The subcommittee, therefore, tentatively recommends the centrifuge, because of its simplicity, adaptability, and convenience, for practical sanitary air analysis.

CULTURE

It is also conceded that, "The efficiency of any sampling method is measurable only in terms of the optimum cultural technique for each bacterial species present and for each variation in the material under test." Most dust organisms are saprophytes which grow well on plain culture media. In determining the count either of bacteria-bearing particles or of total organisms, the subcommittee has adopted media used by the New York State Department of Health in sanitary analysis.

Though nasopharyngeal parasites—specifically hemolytic streptococci of the nose and throat—are more fastidious, they grow well in media containing proteose and tryptose. Blood agar containing these ingredients becomes selective with the addition of 2 p.p.m. of gentian violet, which inhibits most common staphylococci in air; it is hardly necessary to complicate the medium with substances for inhibition of Gram-negative organisms—most of which are short-lived in air. Organisms enriched in proteose-tryptose broth, containing lactose and brom thymol blue to indicate acid production, and also $\frac{1}{4}$ p.p.m. of gentian violet to inhibit staphylococci, may be transferred to selective media for confirmation. Tubes showing acid in 24 or 48 hours are streaked on the gentian violet blood agar, hemolytic organisms being further confirmed as Gram-positive.

SUMMARY OF STANDARD BACTERIOLOGIC PROCEDURES

- I. Density of bacteria-bearing dust particles
 - A. Area count per sq. ft. per min.
 - (a) 15 min. Petri dish count (rough approximation of bacteria-bearing dust particles per cu. ft.).
 - B. Volume count per cu. ft.
 - (a) Slit sampler
 - (b) Air centrifuge, solid media
- II. Settling velocity (ft. per min.) $V_g = A/B$
 - (a) Particle diameter in microns = $13 \sqrt{V_g}$
- III. Total bacteria per cu. ft.
 - C. Amer. Public Health Assn. methods
 - (a) Washings from filtration

- VII. Measurement of sanitary ventilation by sampling at center of room test organisms atomized into four quadrants
 - (a) Dieaway method
 - (b) Equilibrium method

INTERPRETATION

Information obtained by items I to V characterizes bacteria-bearing dusts; the determination of volume and area counts (by I), and their ratio (by II), determines settling velocity and particle diameter. Coarse dust particles indicate atmospheric turbulence rather than dust accumulation, and the presence of particles with high settling velocity indicates activity in a room; so area and volume samples should be taken simultaneously.

The "total" bacteria per cu. ft. (by III) indicate on the other hand

dust accumulation as well as air disturbance. Bacterial masses in dust fragments from contaminated fabrics, or dirt tracked into the room on shoes, are indicated by high average number of bacteria per particle (IV). Where dust arises from infected persons, clothing, or bedding, as in hospital wards and to a less degree in barracks where men are housed under crowded conditions, dust may have special significance. This index of air dirtiness may be useful in judging the efficiency of dust suppressive measures.

The determination of beta hemolytic streptococci on blood agar plates (by V) has received considerable attention in recent years. Compared with the total number of streptococci determined by dilution methods, beta hemolytic streptococci collected on plates may provide additional information upon sources of infection. Also the epidemiology of air-borne infection, in so far as the clinical pattern is determined by the penetration of particles into the respiratory system, depends upon particle size as indicated by settling velocity.

Breathing droplet nuclei constitutes *prima facie* evidence of the exchange of respiratory organisms—the principal hygienic hazard of confined air. This measurement of occupation load upon ventilation by special techniques is a major task of sanitary air analysis. The test for respiratory organisms (by VII) in breathing air will, as did the test for intestinal organisms in sanitary analysis of drinking water, therefore become the most useful bacteriological procedure in ventilation surveys of public gathering places—movies, schools, department stores, factories, and other places of work and recreation.

Evaluation of methods of control of air-borne contagion will ultimately be based on measurement of sanitary ventilation (by VII) after threshold sanitary ventilation has been established epidemiologically.

New Levels of Professional Compensation Set in Veterans Administration

Public Law 293, now in effect in the United States, creates in the Veterans Administration, Washington, a Department of Medicine and Surgery under a chief medical director. Major General Paul R. Hawley, M.C., U.S.A., has been designated to serve as Chief Medical Director. Professional personnel is set up under the Chief Medical Director in an organization resembling the corps service of the Army, the Navy, and the Public Health Service. General Bradley, the chief of the Veterans Administration, has announced that there is an immediate need for 1,125 physicians, 1,200 nurses, and 100 dentists.

Public health workers will be specially interested in the salary levels set for these clinical specialists. The chief medical director will receive \$12,000, a deputy medical director will receive \$11,500 and eight assistant medical directors will be paid \$11,000 each.

In the medical service the Chief grade carries salaries \$8,750 to \$9,500; Senior

grade \$7,175 to \$8,225; Intermediate grade \$6,230 to \$7,070; and the "Full grade" \$5,180 to \$6,020, with Associate and Junior grades at lower levels.

Appointments of the executives will be for a four year term, subject to removal by the administrator for cause. Specialists certified by the Veterans Administration may be paid a salary up to a limit of \$11,000. Promotions will be made on recommendation of special Veterans Administration boards, which will operate like the selection boards of the Army and Navy for higher ranking officers.

This plan will also involve setting up a series of residencies in Veterans Administration hospitals where younger physicians may qualify to become specialists. It is believed that this will serve to raise substantially the quality of medical care available to veterans and it will be similar to the system now in effect in the larger medical centers.

Microbiological Examination of Foods*

Tentative Methods for the Microbiological Examination of Frozen Foods

Food and Nutrition Section

THE processing and use of frozen food products has increased to large proportions and, with the perfection and availability of freezing and storage facilities, should continue to increase. The following tentative drafts represent methods which have proved workable and, while by no means complete, will form the basis for the perfecting of standard methods for frozen foods. Modifications and improvements will be effected as more experience in this field is gained.

In testing frozen vegetables for microbiological content, consideration must be given to the fact that freezing storage at temperatures of approximately -10°F. (-23°C.) brings about a reduction in viable microorganisms. This may amount to roughly 50 per cent in 6 months or 75 per cent in 1 year. Thus, while a high bacterial plate count on frozen vegetables may be taken as proof of poor sanitary history, a low or moderate count does not by itself prove the opposite.

It is recommended that in the preparation of samples of frozen fruits and vegetables for microbiological analysis a mechanical "blender" be employed. This has been arrived at after considerable experience with various methods of preparation on a wide variety of frozen products. In comparison with washing or hand grinding the mechanical disintegration will, as a rule, yield higher bacterial counts. However, more uniform results will be obtained, and the method is less laborious. Simi-

larly the choice of tryptone glucose extract agar rests on the demonstrated superiority of this medium over nutrient agar or glucose agar, although glucose agar as a medium for frozen peas appears to be only slightly inferior.

Examination of Frozen Vegetables— Selection, transportation, and storage of samples

Select from the lot to be examined a suitable number of packages, say 3 or 4, from each code lot of the pack. Transport in dry ice to the laboratory for analysis and place the samples in a refrigerated (0°F.) storage chest until they are to be analyzed. The temperature preferably should not rise above 0°F. (-18°C.) in the handling of the material.

Preparation of Sample:

*A. Peas, Lima Beans, Cut Corn,
Whole or Regular Cut Green
Beans, etc.*

1. *Macroscopic examination*—
Open the package and note condition of the product, especially if ice crystals are present on the inner walls of the package and the vegetables appear to be somewhat shriveled. This condition is indicative of thawing and subsequent refreezing. Record observations and any abnormalities, such as unnatural color or odor, or pink colonies of torulae which are indicative of improper handling practices.

2. *Sampling for plate counts*—
The sample, if not loose-frozen, should

* Report of the Committee on Standard Methods for the Microbiological Examination of Foods.
COMMITTEE ON MICROBIOLOGICAL EXAMINATION OF FOODS.

Organized 1932. Published reports: *Year Books*, 1935-1936, 1937-1938, 1941-1942, *A.J.P.H.*, June, 1943; August, 1945.

be broken up into small units. This can be done by tapping the unopened package sharply against the table edge or by sharply striking the package with a dull instrument, being careful not to break open the package. After opening the package remove sample with sterile spoon, taking the sample from various parts of the broken out package—e.g., from the center and corners.

A 50 gm. sample is aseptically weighed into a sterile borosilicate glass mechanical blender jar; 450 ml. of sterile water is added to the jar and the contents of the jar blended for 2 minutes. If a Variac transformer is available it is advisable to increase the speed of the motor gradually and then run the blender for the required time at the 110 V. setting of the transformer.

Allow the sample to stand for 2 to 3 minutes to permit foam to subside.

Pipette 1 ml. of the mixture into a 99 ml. sterile water blank. Replace the cap on the dilution bottle and shake the bottle briskly 25 times through a 1 ft. arc.

Pipette 1 ml. aliquots of this mixture into each of two Petri dishes (1:1,000 dilution) and also 0.1 ml. aliquots into each of two more Petri dishes (1:10,000 dilution). A 1:100 dilution may be obtained by pipetting 0.1 ml. aliquots of the original mixture into each of two Petri dishes.

Pour melted tryptone glucose extract agar (pH 7.0) cooled to 45° C. into the Petri dishes immediately, and thoroughly mix the dilution water with the agar by gently rotating the plates in a figure 8 motion with slight tilting of the Petri dish. Cool to harden, invert and incubate at 32° C. for 4 days.

Dilutions of 1:100, 1:1,000, and 1:10,000 will usually suffice for commercially packed frozen vegetables, although further dilutions should be made if the history or the appearance of the samples warrant.

It is of prime importance that the

agar be poured immediately after the inoculum is introduced; otherwise many bacteria will adhere to the glass and an inaccurate count will result.

After the incubation period is complete the plates are counted, using a suitable colony counter. Results are recorded as "Plate count of microorganisms per gram."

3. *Direct microscopic count method*—The direct microscopic method has an advantage over the plate count method in that it is quicker and requires less equipment and glassware. Also it detects dead microorganisms, and indicates sanitary history, irrespective of the viable count.

Weigh 50 gm. of the vegetable (peas, lima beans, and cut corn) into a 250 ml. iodine flask.

Add 100 ml. water, stopper flask, and shake briskly 50 times through a 1 ft. arc. Using a Br ed pipette, transfer 0.01 ml. of the washings to a microscope slide and, using a needle, spread the drop evenly over a 1 sq. cm. area of the slide. Dry and fix with heat or with methyl alcohol. Stain with Gray's double dye stain,¹ or with North aniline oil methylene blue stain,² rinse, dry, and examine under the microscope, using oil immersion. Use an ocular micrometer, such as a Whipple disc or Howard disc, with the microscope tube so adjusted that the side of the graduations is equal to 0.1 mm. (area of field 0.01 sq. mm.). Count the cells in 100 fields, and multiply the number by 20,000 to bring to the gram sample basis. Express results as "Direct microscopic estimate, microorganisms per gram."

In the direct method the following assumptions are made. (A) That all the cells are removed from the surface of the vegetable by the washing, (B) that the suspension of bacterial cells is uniform, and (C) that the drop of liquid is evenly spread over 1 sq. cm.

Interpretation of results — Plate

counts of more than 400,000 per gram of peas or direct microscopic counts of over 1,000,000 per gram may be considered indicative of poor sanitary conditions in the plant, or poor handling practice in transit or in warehousing. In regard to other frozen vegetables it would appear that counts tend to run higher. In vegetable freezing plants plate counts of over 500,000 per gram of newly frozen produce are not encountered unless there is some degree of carelessness in the plant, such as faulty clean-up practice or prolonged holding of the material after blanching.

B. Frozen Spinach

For proper comminution of spinach in a "blender" it is necessary to allow the package of spinach partially to defrost by standing at room temperature for $1\frac{1}{2}$ to 2 hours. Open the package and weigh 50 gm. of the contents into a sterile borosilicate mechanical blender jar. Assemble the sample from various portions of the package, taking care to select petiole and blade portions in about the same ratio as in the sample as a whole. Add 450 ml. sterile water. Blend for 2 minutes, and proceed as in analysis of A, peas, lima beans, etc.

C. Frozen Broccoli and Cauliflower

Allow partially to defrost at room temperature. Using a sterile scalpel, cut portions from the curd and stem of several representative pieces of the vegetable. Aseptically transfer 50 gm. of these portions into the sterile borosilicate glass mechanical blender jars, add 450 ml. sterile water, and proceed as directed for A, frozen peas, etc.

D. Frozen Asparagus

Partially defrost at room temperature. Cut spears into short lengths, using sterilized scalpel. Transfer aseptically 50 gm. of the segments into a sterile borosilicate glass mechanical blender jar, add 450 ml. sterile water, and proceed as in analysis of A, frozen peas, etc. When weighing out sample portions, a number of spears should be

selected and the proportion of butts and tips maintained.

The "cuts and tips" type of asparagus pack can be weighed directly into the blender cup.

Examination of Frozen Fruits

Preparation of Sample

Hold the package of frozen fruit at room temperature for 1 to 2 hours before opening in order partially to defrost the contents. While the fruit is still partially frozen, cut portions from various parts of the contents of the package, using a sterilized scalpel. The proportion of fruit to syrup should approximate that of the whole package. Weigh 50 gm. of fruit and syrup into a sterile borosilicate glass mechanical blender jar. Add 450 ml. sterile water, and blend for 2 minutes. Make a 1:1,000 dilution by adding 1 ml. of the blended mixture to 99 ml. sterile water and further dilutions in the usual manner. Plate 1 ml. portions from the various dilutions on tryptone glucose extract agar. Incubate for 3 days at 32° C. Colonies are counted under a suitable colony counter. Record results as "Plate count of microorganisms per gram."

Direct microscopic counts for molds and yeasts are made according to the methods given in *Official Methods*, A.O.A.C.³ for microscopic analysis of tomato products. Care must be taken to distinguish between mold hyphae and fruit setae.

LETTER TO THE EDITOR

TO THE EDITOR:

I have been told that a set of Journals representing the numbers of the *American Journal of Public Health* published during the war years, which were lost when our Medical Library was burned during the Battle of Manila, are to be given by the American Public Health Association to the Institute of Hygiene at Manila for the use of public health workers in the Philippines.

May I express our gratitude to the Association and to its members for this demonstration of thoughtfulness which is characteristic of the big-hearted way your people act. While I am in this country I want to say on behalf of my colleagues in the Philippines that the donation is very gratefully appreciated.

Sincerely,

HILARIO LARA, M.D., DR.P.H.

*Member Philippine Public Health
Association and Philippine Medical
Association; Director, Institute of
Hygiene, Manila, P. I.*

(The Association continues to receive copies of the Journal made available by members for other libraries overseas like those in the Philippines. The Association is constantly being reminded of the enormous value which such Journals have in devastated countries.)

Selective Service Rejection Statistics and Some of Their Implications

G. ST. J. PERROTT, F.A.P.H.A.

Division of Public Health Methods, U. S. Public Health Service, Washington, D. C.

PRESIDENT TRUMAN in his Health Message to Congress on November 19, 1945, reported that the Selective Service System has brought the widespread physical and mental incapacity among the young people of the nation "forcibly to our attention in terms which all of us can understand."

"As of April 1, 1945," the President stated, "nearly 5,000,000 male registrants between the ages of 18 and 37 had been examined and classified as unfit for military service. The number of those rejected for military service was about 30 per cent of those examined. The percentage of rejection was lower in the younger age groups and higher in the higher age groups, reaching as high as 49 per cent for registrants between the ages of 34 and 37. In addition, after actual induction, about a million and a half men had to be discharged from the Army and Navy for physical or mental disability, exclusive of wounds; and an equal number had to be treated in the armed forces for diseases or defects which existed before induction."

These facts are not new, as the President pointed out. Health authorities have been concerned about the serious state of ill health among American youth since late in 1941 when the Selective Service System published its first analysis of the health status of inductees. In this paper it is proposed to discuss the validity of the data as a measure of the prevalence of physical and mental defects and diseases, with

particular reference to changes in prevalence which have occurred since 1918. The data will be examined with a view to estimating the significance of these findings to public health.

Rejection rates must be a first consideration in any evaluation of Selective Service findings. These rates varied greatly during the war. In the first year of Selective Service, registrants were given complete physical examinations by local board physicians. Those who were found to be fit were sent to Army induction stations for final physical examination and, on the basis of this latter examination, were accepted or rejected for military service. Rejection rates for this period (November, 1940, through September, 1941) averaged 52.8 per cent of all men examined. Following Pearl Harbor, a marked reduction was noted. This was probably due to pressure on local boards and induction stations for additional military man power.

By January, 1943, the rates reached an all-time low of 28 per cent. They rose gradually during the year, however, reaching a high of 42 per cent during the last four months of 1943. The increase is attributed mainly to: (1) a higher age average among men examined, and (2) a higher proportion of previously rejected men among examinees as local boards reclassified registrants in an effort to meet their quotas.

The decrease in the rejection rate from 42 to 31 per cent by the end of

the first five months of 1944 resulted largely from two conditions. The average age of men examined was lower than in the previous period, and examination facilities at induction stations were taxed by unusually heavy in-pourings of selectees.

Rejection rates began again to increase by the middle of 1944, progressing steadily from 36 per cent in June to 45 per cent in November. The reasons were: induction for limited service was halted in June; and in the same month psychological tests for mental capacity were modified so that some illiterates, who previously would have been inducted, were rejected. Moreover, during this period greater emphasis was placed on the need for inducting men suitable for combat replacements.

These changing procedures affecting the trend of rejection rates illustrate some of the difficulties involved in evaluating the level of national health in terms of acceptance or rejection for military duty. At any particular period the rejection rates tell only the relative number of individuals who did not qualify according to standards of that period. As has been seen, some of these standards had no relation to physical status.

In discussing rejection rates, Col. Leonard G. Rowntree* said: "Rejection rates based upon the number of registrants rejected for military service per 1,000 men examined have limitations in their use as criteria of good civilian health. Rejection rates are dependent upon too many factors, as for instance (1) changes in standards of induction, (2) changing deferment policies, (3) varying numbers of registrants by age, race, urban-rural areas, all of which introduce variables correctable only through the calculation

of specific rejection rates, (4) whether a registrant is coming up for the first, second, third, or fourth examination, and (5) how far military standards exceed those required of normal civilian living. Selective Service, therefore, regards the rejection rate per 1,000 men examined as useful in measuring the nation's health only in terms of the limitations placed upon such rates. The incidence of all recorded defects in accepted and rejected men is a better index of the health picture. The latter is only limited in so far as all defects may not be recorded."

In addition to this limitation, however, there are other elements that must be considered in any attempt to arrive at a true evaluation. These include differences in examining techniques at various examination centers, idiosyncrasies of the examining personnel, and the attitudes of the examinees.

A comparison of the reports for November, 1940, through September, 1941, and for April, 1942, through December, 1943, illustrates the effects of these factors on Selective Service findings of the prevalence of disease and disability.

In the first report 1,583.3 defects per 1,000 men examined were recorded; in the second, 1,000.2 defects for each 1,000 examinees. Between the two periods, the coding procedures were changed so that the complete list of defects was not always available in the 1942-1943 data. Since the defects were summarized in order of significance, the limitations of coding would result in the omission of less significant defects and account, at least partly, for the drop in rate.

The effect of such omission and of the other stated factors can be gauged by a comparison of rates for specific kinds of defects. For example, in 1940-1941 when the coding was more complete and when flat feet were a cause for rejection, foot defects, with an average of

* Chief, Medical Division, National Headquarters, Selective Service System.

FIGURE 1—Recorded frequency of defects and disease reported among Selective Service registrants examined during November, 1940–September, 1941, and April, 1942–December, 1943

172.4 per 1,000 men, led the list of disabilities. By 1942–1943, however, minor foot ailments were considered unimportant, and reporting on this category fell to 54.6 per 1,000 examinees. Similarly, dental defects—averaging 167.8 per 1,000 men—were second highest among defects listed for 1940–1941. By 1942–1943, the incidence had fallen to 113.0 per 1,000 examinees. This, likely, was due to the failure of ex-

amining personnel to record all cases of carious or missing teeth, or to give dental defects sufficient precedence for inclusion in the coding, since these defects no longer were cause for deferment.

Marked decreases also are found in the prevalence of throat diseases, skin diseases, and defects of the abdominal viscera as the need for more military personnel grew urgent and examining

physicians tended to concentrate on the more serious defects. The relatively minor conditions were included as secondary defects only and thus omitted in the coding.

On the other hand, reports of important defects remained fairly constant in 1942-1943. Eye defects, for example, varied only slightly in the two periods. There also was little change in the reported prevalence of neurological diseases, or of diseases of the lung, kidney, and ear. A large proportion of conditions in these groups of defects were outright causes for rejection; and reporting, necessarily, was fairly complete.

The great increase in the incidence of tuberculosis (9.7 to 19.1) is accounted for largely by a change in examination procedure. Chest x-rays did not become an examination routine until 1942; therefore, it is reasonable to suppose that many cases of tuberculosis among pre-Pearl Harbor inductees passed through examining stations undetected.

The wide variations in reports of educational and mental deficiency recorded for the two periods are easily traceable to different definitions of "educational deficiency" in effect during the two periods. Between November, 1940, and May 15, 1941, regulations stated that registrants were acceptable who "appear to have normal understanding, whose speech can be understood, who have no definite signs of organic disease of the brain, spinal cord or peripheral nerves, and who are otherwise mentally and physically fit." During this period, illiteracy was mentioned in the records of 3.6 registrants per 1,000 examined. On May 15, 1941, however, the standards were raised to require that a registrant should be able to "read and write the English language as well as a student who has completed four years in an American grammar school." These standards re-

mained in force until April 1, 1942. As could be expected, rates for educational and mental deficiency rose in the period.

Mental disease, which was high among the more serious defects in both periods, was found in 67.5 men out of every 1,000 examined in 1942-1943. At the top of the list among these diseases were psychoneurotic disorders, psychopathic personality, and grave mental or personality disorders. Since serious attention was given by examining physicians to evidence of mental disease in both periods, and since the reports for the periods are consistent, it could be concluded that reporting and coding of the incidence of mental disease was fairly accurate.

These comparisons bring out the fact that the order of defects may have been closely associated with prevailing regulations for the rejection or acceptance of examinees for military service. The judgment of the individual examiner in evaluating the relative importance of a series of defects also must be considered as a factor in determining the listing. It is likely, then, that reporting on many defects varied as Selective Service regulations changed; that recording of *secondary defects* tended to be overlooked as coding procedures were simplified, and that the opinion of examining physicians in classifying defects according to relative importance was associated to some degree with military standards.

Review of the figures leaves little doubt that the findings for 1940-1941 more clearly approach the actual prevalence of defects, although how close that approach is can only be guessed. There seems reason to believe that the figures present a fair picture of the prevalence of major defects—with allowances made for variations in examining techniques, in the judgment of examining physicians and in the recording and coding of defects. It also seems obvious that the many factors which

influenced the recognition and recording of secondary defects detract from the accuracy of the reports.

None of the factors which have influenced the reporting and coding, however, obscures the enormous volume of defects. Since all defects—whatever their nature or degree of concern to military authorities—are of importance to the individuals affected, the findings of Selective Service pose a public health problem which must be solved before good health can be achieved for the population.

Too much emphasis is still placed on the decline in mortality as a measure of achievement in health work. Death is by no means the sole measure of the level of national health. To raise the health level, it is essential that increased attention be given to preventing and curing those conditions which cause illness or which reduce the capacity of the individual.

Since the last war the national mortality rate has declined by 3.1 per 1,000 population. Among young men 20 to 34 years, the death rate has gone down nearly 30 per cent. One could feel more complacent if this reduction in mortality were associated with an equal reduction in disability. But such is not the case as comparison of the findings in World War I with those of World War II illustrates.

Reports on the prevalence of defects in the first war show that 661.9 defects were recorded per 1,000 men examined—in contrast to 1,000.2 defects per 1,000 in 1942–1943 and 1,583.3 in 1940–1941. Just as the differences between the 1940–1941 and the 1942–1943 data are due largely to the coding of the diseases, so it must be suspected that failure to record many minor defects in World War I accounts for a major part of the discrepancy in the records of the two wars. In addition, differences in the medical terminology of the two periods make it difficult to determine the

exact classification of defects in many instances. Diagnosis of a number of diseases also underwent refinement in the interval between wars.

As a result, although wide variations in some general groupings will be noted, differences in specific categories, where similarity in terminology permits comparison in the two periods, are not always as great as might be expected. Among diseases of the eye, for instance, 61.0 defects per 1,000 men examined were found in 1917–1918, against 123.5 in 1940–1941. Yet for bilateral and unilateral blindness—an easily defined defect which can be assumed to have been reported in the same category for both wars—the difference is small. Similarly, there is only small variation in recordings of the incidence of trachoma and the slight decrease noted in 1940–1941 may point to some public health accomplishment in the conquest of this disease.

Increased medical knowledge is a factor that cannot be overlooked in comparing the incidence of a number of defects. This is particularly true of asthma, cardiovascular disease, and venereal disease. Since diagnosis of these conditions is much more frequent throughout the population today than twenty years ago, it follows that the incidence among a selected group in 1940 should be greater than in 1917.

Variations in the incidence of tuberculosis are of especial interest since examination procedures in effect in 1940–1941 more closely approximated those of 1917 than in any other period of World War II. Moreover, the decline in incidence rates for the two periods bear fairly close resemblance to the drop in the national tuberculosis mortality rate between 1920 (113.1) and 1940 (45.9). Since the incidence of tuberculosis increased markedly with the inauguration of chest x-rays as an examination routine—moving to 19.1 per 1,000 men in 1942—

TABLE 1

*Prevalence of Certain Recorded Defects Among Drafted Men,
World War I¹ and World War II²*

Diseases or Defects	Rate per 1,000 Men Examined	
	World War I	World War II
All diseases or defects	661.9 ³	1,583.3 ³
Eyes	61.0 ³	123.5 ³
Blindness, bilateral and unilateral	7.5	6.5
Trachoma	1.2	0.5
Defective vision	46.3	83.3
Ears	15.4 ³	50.1 ³
Defective hearing	7.1	9.4
Otitis media	7.3	8.3
Asthma	2.3	5.4
Hypertrophic tonsillitis	33.8	44.1
Tuberculosis (all forms)	24.7	9.7
Cardiovascular	50.2 ³	83.1 ³
Valvular diseases of the heart	29.6	12.7
Cardiac hypertrophy	4.2	2.8
Tachycardia	5.0	6.7
Hernia and inguinal rings	55.4	79.7 ³
Hernia	27.6	34.8
Enlarged rings	27.8	34.4
Veneral diseases	46.7	38.1
Gonorrhea	36.0	7.1
Syphilis	9.5	30.8
Chancroid	1.2	0.2
Varicose veins and varicocele	8.8	32.1
Mental deficiency	12.2	15.3
Epilepsy	3.9	3.7
Mental alienation	3.8	16.3
Crippled or paralyzed members	48.7	76.8
Lost members:		
Upper extremities		
Fingers	7.6	7.1
Other	1.6	1.5
Lower extremities	4.6	3.6
Flat feet	104.4	162.0
Curvature of the spine	7.7	15.0

¹ From Table 4 in Britten, R. H., and Perrett, G. St. J., Summary of physical findings on men drafted in the world war. *Pub. Health Rep.*, 56:41-62, 1941.

² From Table 7 in Selective Service System, Causes of rejection and incidence of defects. *Med. Stat. Bull.* No. 2 (Aug. 1), 1943.

³ The sum of the rates for specific categories of defects does not always add to the rate for the general category because of the omission of specific categories not comparable to the two periods: World War I and World War II.

1943—it seems evident that (1) considerable tuberculosis went undiscovered in 1917-1918, and (2) that the incidence of the disease actually was lower in 1940 than twenty years previously.

Loss of members is an obvious defect that cannot be influenced by any of the elements affecting reporting or diagnostic procedures; therefore, these figures can be accepted at face value. The great similarity in rates for this type of defect, as well as for others which are easily observed, leads to the con-

clusion that the prevalence of a number of defects in 1917 was probably about the same as in 1940-1941.

Certainly, evidence of great improvement is not reflected in the comparison. While slight decreases may be indicated in the incidence of a few defects and diseases over the twenty year period, they are too small to be proof of progress. Examination of the findings of World War I and World War II, then, seems to attest to the conclusion that the health level of the American people

has not improved in the same degree as mortality for at least two decades.

The central fact remains that the findings of both wars show an enormous amount of ill health in the population.

During and after the first World War, draft data were reviewed, analyzed, and interpreted. Over the ensuing years, medical statisticians decried the low level of health among the nation's young men and viewed the situation with alarm. It is regrettable that the papers produced by these statisticians represent the sole use to which the findings of World War I were put.

Now, once more, protests are being raised against the health level—this time based on the amount of defects found among the sons of World War I examinees. It is to be hoped that the implications of these latest wartime health reports will be regarded as an index of the degree of actual need and will be utilized in planning health services which must be supplied to bring to oncoming generations the benefits of knowledge already at hand.

Reports of defects found among young men examined for military duty in World War II can serve as signposts to health authorities in plotting future activity. Much of the past achievement in public health has been due to the application by health departments of epidemiological case finding techniques to the control of disease spread. Selective Service data make available a new source of information for evaluating the relative extent of particular physical and mental defects.

The President in his recommendations to the Congress for the establishment of a National Health Program has used the reports on medical examinations of selectees to gauge the total health needs of the country. Nation-wide programs for the prevention and cure of tuber-

culosis, venereal diseases, and other communicable diseases are now authorized by the Congress. State and local health authorities can use Selective Service findings to ascertain where existing programs should be strengthened and what additional services are required. In the past, health authorities have turned to mortality rates as a major index for determining problems of public health significance. The limitations of these rates in evaluating health needs have been recognized. Knowledge provided by mortality statistics is confined to deaths resulting from specific diseases. A well organized attack on the whole health front requires comprehensive and current information on the prevalence of disease and defects—in short, complete morbidity reporting in every state. In lieu of this, Selective Service data, while not so accurate, offer an immediate and potent source of information on the prevalence of those defects which it is within the province of public health to prevent or remedy.

Chronic Disease: A Problem That Must Be Faced*

EDWARD S. ROGERS, M.D., F.A.P.H.A.

Assistant Commissioner for Medical Administration, New York State Department of Health, and Director of Planning for the Care of the Chronically Ill, New York State Health Preparedness Commission, Albany, N. Y.

THERE are few major problems in the field of medical and social need about which there is more universal agreement and, yet, about which less actually is being done than that of the care of the chronically ill.

The fact that this need has existed so long and that the deplorable lack of adequate facilities for the care of the chronically ill has not evoked more attention may be explained, in part, by the gradual shift in our pattern of domestic life from that of a predominantly rural population in which we were inclined and able to take care of our needs in our own homes to that of urbanization, industrialization, and crowded housing; in part, by the steady increase in the age of our population resulting in increasing opportunity for the development of the so-called degenerative diseases and other diseases associated with age, such as cancer; and, in part, by the unfortunate fact that the chronically ill are, generally speaking, unable to organize so as to bring about the fulfillment of their needs. There are, of course, other factors involved; these are merely illustrative.

As might be expected under the circumstances, the efforts of communities to meet this growing problem have

resulted in developments on a more or less haphazard pattern.

Today we are approaching an era of medical social enlightenment when, perhaps for the first time, we may expect to see the meeting of minds and unification of purpose necessary to an integrated approach to this complex problem. There are abundant signs: the broadening of our social security provisions, the increasing concern for all of the basic needs of our population, and the new understanding of the social forces in illness and disease and concepts for their prevention.

The undesirable conditions being called to our attention at the present time, exemplified in the very inadequate facilities for the care of the chronically ill in many county home infirmaries and nursing homes, do not necessarily constitute a condemnation of our social system if understood in the light of their origin, but they would constitute a condemnation of it were they allowed to continue. In some areas steps actually have been undertaken to meet these needs, but, generally speaking, these steps have been restricted to specific communities and groups where rather specialized circumstances obtain or to only a few of the essential phases of a complete program. They do not provide us with the complete pattern or the means for answering the total needs of the chronically ill, be they

*Presented before the Victory Meeting of The Public Health Association of New York City in conjunction with the American Public Health Association, New York, N. Y., December 14, 1948.

rich or poor, urban or rural, young or old, or of one religion or another.

For planning purposes, some sort of a definition of chronic illness seems to be required. Certainly definition is essential for understanding the significance and comparability of the limited data available. For example, the National Health Survey¹ defines chronic disease as "a disabling or non-disabling chronic pathological condition known to the informant, the symptoms of which had been recognized for at least three months." There are obvious flaws in this definition. A patient with newly recognized and diagnosed diabetes or rheumatic heart disease would not be eligible for inclusion under this definition until three months had elapsed. But, for practical purposes, it is difficult to make a definition that does not have flaws.

When it is estimated, on the basis of the National Health Survey,² that 25 million persons, or one in every five persons in this country, has a chronic disease, we are not particularly impressed for we know that many of us are included in this group but that we get around somehow in spite of it. When we learn that it is estimated that over 1.5 million persons are permanently disabled from chronic diseases (exclusive of those confined to long-term care in mental or tuberculosis hospitals), that almost one billion days each year are lost from work or other usual pursuit because of chronic illness, and that more than three-quarters of the chronic disease cases are among persons in the productive years from 15 to 64,¹ we are undoubtedly more impressed—but still not moved to action.

But there are other ways of learning that there is a problem and what the nature of the problem is. Visits to the wards of a few large general hospitals, conferences with social workers who are desperately trying to find places for the chronically ill, visits to county

homes, talks with welfare officers, with public health nurses, or with almost any physician, are more substantially convincing of this unmet need than cold figures that are so difficult of interpretation.

There is no intention to detract from the importance of studies and surveys. They have a most essential rôle. Significant and excellent studies have been made nationally as mentioned¹; locally, such as the studies of Boas³ and Jarrett⁴ in New York City, and of Jarrett⁵ in Cleveland; at the state level, such as the study of Bigelow and Lombard in Massachusetts in 1929-1931,⁶ the 1944 report of the Public Welfare Council of Connecticut,⁷ the report in 1932 of the New Jersey Department of Institutions and Agencies⁸; and there are undoubtedly others. These constitute valuable documentation of the need and undoubtedly have given and are continuing to give important support to public action. It is doubtful, however, that they can determine it.

The point that should be made is this: those of us who are faced with the problem of doing something for the chronically ill today probably would be poorly advised to start with a survey to determine the specific character and extent of chronic disease in our respective areas. There would be danger of getting "bogged down" in a time consuming project which really would not add much to what has already been demonstrated adequately. Certain fundamental services for the chronically ill are obvious and beyond question as to their value and need. It would seem, therefore, to be good sense to start with them and to provide them. At first, this should be done in a small way, well within the limits of what is known to be needed. Step by step thereafter, further progress should be made as needs and relationships define themselves. The end result will be:

first, that something will be done to meet this need—and a few enlightened places are already ahead of most of us in this respect—and second, that we shall finally accomplish a program that is thoroughly practical and thoroughly consistent with other related programs and services. In other words, the question resolves itself into one of the fundamentals of program planning and development.

First, the objectives must be established. What areas and what groups of the population are to be covered? Generally speaking, it would seem that this is a proper field for state-wide action. The inadequacies in existing facilities for the care of the chronically ill are about as great for those of modest means, or even the well-to-do, as they are for the poor. The planning for facilities and services of high standard should embrace the needs of everybody. The question of paying for them can and should be dealt with separately. In this latter connection, the potential economic relief that may be achieved from medical care insurance should not be confused with the equally great need for an improved distribution of facilities and services and the maintenance of their quality. Insurance *per se* will make little contribution to either of these.

If the matter of definition cannot be avoided, and it probably cannot, an attempt should be made to make it as flexible as possible. Actually, not everyone with a chronic illness is ill in a functional sense; and, while it might be a fine thing to have each one registered and under medical observation, such certainly should not be an early objective of a program.

Therefore, an administrative definition of chronic disease suggests itself as follows: A disease that may be expected to require an extended period of medical supervision and/or hospital, institutional, nursing, or supervisory

care. Such a definition would be utterly useless in obtaining prevalence data; yet it embraces the problem in terms of services needed, and it is with these that we are primarily concerned. It is, indirectly, a functional classification. If a functional classification were possible in all categories of chronic disease, such as that prepared by the Criteria Committee of the New York Heart Association for the classification of heart disease, chronic disease morbidity data would acquire a new meaning.

Second—and this point cannot be emphasized too strongly—planning for the care of the chronically ill should be considered as a most important segment of, and in no way separable from, planning for medical, preventive, and health service as a whole.

There is a strong tendency to approach the problem from a traditional point of view and to consider it a matter of public assistance. It has very real public assistance aspects. These must be fully recognized; but it would be most unrealistic today to undertake to develop divided medical and health services for this or any other area of medical need on the basis of whether the patients themselves are to pay for service, or whether someone else is to pay for them. The medical and health needs of the poor, the near-poor, the well-to-do, the civilian and the veteran, the laborer and the farmer are quantitatively and qualitatively one entity; and good planning will recognize them as such. As has been pointed out already, this principle bears no obligation to the controversial problem of who is going to pay for the service. It bears a distinct obligation, however, to the problem of administrative structure.

Also, there is a tendency to approach the problem of chronic illness as though it were medically isolated—one that indicates the construction of distinct institutions for the care of the chronically ill—much as was done for the

care of the tuberculous and the mentally ill. Yet, many authorities in these two fields are now openly critical of their earlier judgment and see their problems as specialized parts of, but not remote from, those of medical and hospital care as a whole.

In the light of the current emphasis on the construction of coördinated hospital and health center facilities and the very real prospect of national and state legislation and planning, it certainly is urgent that the needs of the chronically ill be kept in mind. It is equally urgent that those planning for the care of the chronically ill, if they happen to be a jump ahead of the state master plan, make their plans adaptable to the fundamental future pattern.

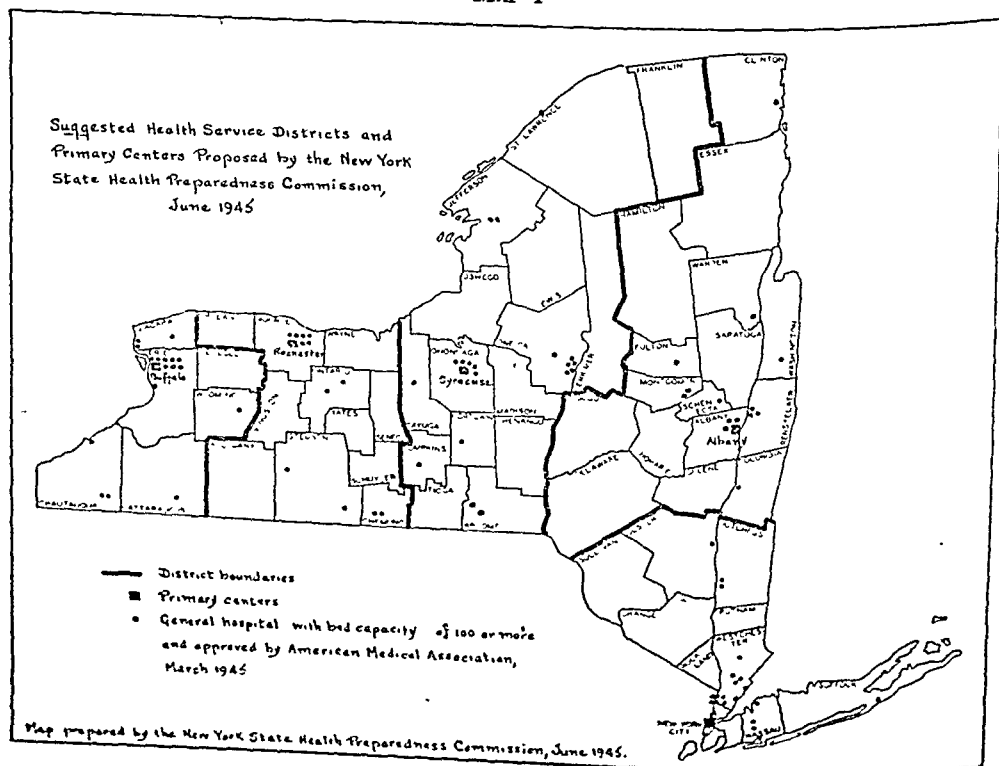

Because we felt so strongly about this and believed that a plan for the care of the chronically ill in New York

State* should be fully adapted to a long-range plan for all services, our first attention was given to a study of logical grouping and regionalization of medical services as a whole.⁹ We have defined five natural, primary medical centers in New York State and tentatively visualized the areas which they most logically would serve (Map 1). Also, entirely tentatively, we have indicated the possible localization of so-called secondary medical centers which correspond to the district hospitals in the plan devised by the U. S. Public Health Service and presented in the so-called "interim report of the Pepper Committee" in January 1945.¹⁰

The fundamentals of this general plan for the integration of hospital and health facilities in a qualitative relationship are well known. It has stood

* Reference is to the Plan for the Care of the Chronically Ill being developed by the New York State Health Preparedness Commission.

MAP 1

the test of a good deal of thinking and discussion as well as a certain amount of practical demonstration, and it should be kept in mind in planning for the care of the chronically ill no less than in the planning of any other medical and health service.

With the recent appointment by Governor Dewey of a Joint Hospital Board for New York State, which is to conduct a survey and develop a state-wide plan for hospital and health center facilities, our planning group has turned over this phase of its work to the new board and we shall look to them for further guidance. The essential point is that we shall integrate our plans with theirs. Similarly, the value of and need for such integrated planning must be impressed upon all communities of the state in order to assure as much lasting benefit as possible from the post-war hospital, county home, and other institutional construction mania that have seized upon us.

Third, the general character of the services required must be agreed upon. There are different levels of need in relation to the care of the chronically ill, and not all of them can be handled in an identical manner. Three levels have been suggested by Boas¹¹ as follows:

1. Diagnosis and treatment
2. Skilled nursing care
3. Custodial care or home care

It would be extremely difficult to predict the distribution of the chronic disease case load among these three levels of service for any given community. There is bound to be considerable overlapping. For example, patients in nursing institutions or county infirmaries unquestionably will shift in medical status and will require more intensive care in the hospital for short periods. On the other hand, some may improve and require no nursing supervision. Hence, provision must be made for reasonable interchange,

and prediction of the case load would be difficult unless precise criteria first could be established for the admission or transfer of patients from one category of care to another. It seems quite obvious that this could not be done arbitrarily and, if done at all, should be sensitive to variations in the local situation that relate to it.

It is hard to decide just what type of hospital facilities are most needed. One point is certainly clear, however, and that is that under present conditions there are not sufficient beds for the hospital care of the chronically ill, and general hospitals do not like to take or keep them.

Without any intention of being dogmatic about a subject concerning which there undoubtedly is room for argument, the following suggestions, which seem to have much in common with the recommendations of Bluestone,¹² are set forth as seeming to be desirable:

1. The chronic disease hospital, as distinct from a nursing or custodial institution, should be located in a medical center offering all essential diagnostic skills and facilities.

2. The chronic disease hospital should be an integral part of a general hospital, physically close to it, but administratively reasonably independent. There should be complete identity of medical staff and interchange of resident physicians.

3. The chronic disease hospital should offer services and facilities of very high quality to everybody requiring such. The basic standards should be determined, in the first instance, by the State, and, beyond that, through such additional requirements as local circumstances shall permit and as shall be determined locally.

4. In general, patients should be kept in the chronic disease hospital for relatively short periods for the purpose of diagnosis and intensive therapy, or for longer periods of time if desirable for study, research, or rehabilitation.

5. The second level of care should be provided in decentralized institutions conducted as nursing homes or infirmaries. These should have sections for custodial care, or be closely associated with units operated for custodial care. It would be difficult to separate these two levels completely because of

the shifting of many patients back and forth between them. Moreover, the current pattern for administration of both levels, usually under the welfare departments, is deep-seated and there would seem to be no reason for changing this unless it should prove unworkable.

It hardly need be pointed out that, with respect to technical interest and skilled supervision and care, the chronically ill will nearly always suffer in contrast to the acutely ill when they are side by side in the hospital. The acute problem is more dramatic; it moves faster; it demands and gets more attention from physician, intern, nurse, and student alike. Yet there is no reason why chronic disease should not be made technically interesting. In fact, it must be if we are to attract people to research in this field and provide essential teaching material with a view to preparing the doctor of tomorrow to carry on with his work. Remember that an increasing amount of his work must be in the field of geriatrics.

The outstanding lacking requisite for obtaining interest in chronic disease that is comparable to that in acute disease, would appear to be the provision of a sufficient volume of material. Just as long as the chronically ill are scattered here and there among general hospital cases, their individuality as an intriguing medical problem will be lost. If they are properly grouped in large enough numbers to compensate for the slow motion of the individual case, a field of great clinical and research importance and interest should result. It should be followed by better care, improved methods and knowledge, and a better and more keenly interested medical profession.

At the second level of care, that is, nursing homes and infirmaries, there would seem to be equally great need for new thinking. Generally speaking, the medical and nursing standards in nursing homes, county homes, and poor

farm infirmaries are inadequate. In fact, it is no exaggeration to say that they frequently have been found to be little short of disgraceful vestiges of a much less enlightened time. These problems have been fully discussed and remedies suggested by authorities such as Potter^{13, 14} and Jarrett.⁴

Medically these institutions have a service to perform in providing facilities for the supervision or nursing care of those who do not require the more costly facilities of the chronic disease hospital. The medical services for such nursing homes, infirmaries, and units should be provided through affiliation with the staff of a secondary hospital center or, where that is not feasible, with the highest qualitative level of service that is available. In a proper functioning of the anticipated relationship between the primary, secondary, and outlying medical units there should be active interchange, consultation, and maintenance of standards by the medical staff itself, with the official state agency remaining largely in the background.

There would be much to be gained if these local institutions, for which the title "nursing infirmaries" suggests itself, could be so developed and operated that they could serve the needs of all classes of the population. The fact that most of them are run by the local welfare departments need not preclude this possibility. Potentially paying patients could pay, though application of the means test should be humanitarian. It is the provision of facilities and the assurance of high standards of care for everyone that are important at this time.

Also, there is no reason why private nursing homes should not be utilized, provided, of course, they meet standards of facility and staff. Generally speaking, however, these units are too small to provide the necessary services without unreasonable cost.

In addition to institutional facilities, a complete plan for the care of the chronically ill should embrace provision for diagnostic and consultation clinic services and follow-up clinics for ambulatory patients who do not require institutional care. There also should be the fullest possible integration of such services with public health nursing services and other local health and welfare activities. Such integration cannot be left to chance but should be included in the substance of the program.

Since this is a public health conference, it probably is unnecessary to emphasize the significance of public health measures and the preventive medical approach to the lessening of the burdens of chronic disease. Certainly if there is any merit in preventive medicine as a concept, it should find a fertile field in the problems of chronic illness.

The problems of financing the construction and operation of the proposed facilities are also complex and the patterns currently in use vary greatly. Pending state and federal legislation may or may not change the entire picture. But regardless of what may emerge, the problems of integration, organization, and administration that have been mentioned will remain to be worked out.

If new legislation sweeps aside the problem of cost, we should be able to move that much more rapidly toward meeting this area of need. If it does not, we shall be faced with the difficulties of working within our current basic structure. Should the latter result, it is important to point out that the federal and many state laws for aid to localities in meeting their public assistance expenses may actually militate against the provision of the best quality care. For example, under the existing provisions, it may prove far more economical for a county to place

its chronically ill in second-rate nursing homes, which are virtually unsupervised, in order to receive substantial reimbursement through federal and state funds, than it would be for it to care for these patients in good hospitals and infirmaries for which it can receive no financial aid.

While this problem may be a bit beyond the province of this discussion, it should be pointed out that a thorough review of federal and state legislation in these respects is most urgently needed.

The provision of the necessary facilities and services admittedly will be expensive. The question may well be raised, however, as to whether it might not prove more expensive to neglect the study and development of means for preventing chronic disease, or at least minimizing the periods of disability resulting from it, than it would be not to do so. This question would seem to be destined to be the increasing concern of government under an expanding social security system. A billion days of disability and unemployment a year will not be cheap! Furthermore, with an aging population, future production may have to depend more upon a sustained working capacity among older persons than is the case today.

In conclusion, it would seem that the time for facing the problem of the care of the chronically ill has come and, while it admittedly is difficult of solution, we are better equipped to meet it in terms of public interest, in understanding of our needs, and in the potentialities for the necessary coordinated action between official and non-official agencies and groups than we have been heretofore.

It is a problem involving the necessity for joint planning among welfare, health, medical, and hospital agencies. Such joint planning should result in the enunciation of a clear set of objectives

and in understanding and agreement with respect to the responsibilities of each. Finally, the fact that the care of the chronically ill is merely a part, albeit a large part, of the problem of medical care and health as a whole must be kept in mind so that such patterns as are developed may be consistent with the further evolution of good medical and health services.

In-service Training in a State Department of Health

FELIX J. UNDERWOOD, M.D., F.A.P.H.A.

Executive Officer, Mississippi State Board of Health, Jackson, Miss.

EDUCATION goes on and on. It is a never-ending process starting from the day of birth and continuing until death. The better it "takes" the more flexible an individual becomes and the greater his benefit from each of his experiences. A few rare souls go through life with an ever-sharpening sense of expectancy, an ever-ripening wisdom, and an ever-increasing understanding. In some mysterious way they manage to keep their feet on the ground and their heads in the clouds. The truth is they are forever educating themselves, making the most of each experience, developing things, working them out, and getting enjoyment, philosophy, and satisfaction from the process.

One educator remarked many years ago, "Our educational efforts are sadly disappointing except when applied to those gifted individuals for whom they are almost superfluous." This point of view leans to the pessimistic side. But it points up the first step in any program of in-service training—careful and considered selection of personnel. Many of our great souls in public health had no formal training. They established the principles by which public health activities are being pushed forward today. These were pioneers, it is true, but there is still room for pioneering in public health. The field has not yet crystallized to such an extent that initiative and enterprise are not needed! May it never be!

It is hard to polish a stone. Recruitment of public health officers, nurses, engineers, sanitarians, clerks, dental hygienists, and health educators is worthy of the best thought and time in any state that the person assigned to do this job in each of these fields can give. Aside from the fact that employment difficulties are decreasing, an admonition to pick carefully still is significant. In certain counties in the country where a well trained health officer joined the military forces, public health might be further along today if he had not been replaced at all, because of the incompetence of his successor. The same is true for some other public health personnel. Programs in these counties have not progressed. Public opinion about the value of preventive medicine may have retrograded.

The war has pointed up the tragedy of improper selection of personnel. But if it has taught us lessons of what cannot be done with people who are improperly recruited, it has brought home forcefully a greater lesson of the flexibility and teachableness of people sincerely motivated to serve their community and fellow man. It has also emphasized the value of job analysis, better direction of professional effort and the use of less skilled people to take over the routine aspects of public health administration, nursing, sanitation, and other work.

In-service training of public health personnel may include any learning ex-

perience of a public health employee, varying from the visit of an advisory consultant to one or more years of long-term public health or related graduate work. It may include attendance at a two day institute for sanitarians on safe methods of spraying DDT, for nurses on techniques in the control of gonorrhea, or for health educators on methods of organizing for mass x-raying of 95 per cent of a county's population. In-service training accrues also to the convention delegate.

Short medical graduate courses in obstetrics, pediatrics, and syphilis offer in-service training to the practising physicians who conduct health department conferences. The visit of a nutritionist to a staff meeting in a county health department with the latest information is in-service training. The young statistical clerk who has an opportunity to go for the first time to the big city and learn about tabulating machines is having a learning experience of real value. The ambitious secretary who takes advantage of a night-school course in stencil cutting and mimeoscoping, journalism, or psychology is improving her personal and financial worth to the organization for which she works.

In-service training includes opportunities for local and state staffs to visit other health departments, observe procedures in other counties and states, and to return with new enthusiasm and ideas to the job at home. Training center apprenticeship for anywhere from a few days to a few months with formal classes and field experience is part of in-service training, as are short courses in public health and related fields at schools of public health and universities. Long courses in public health and all of its specialized branches, including not only communicable diseases, maternal and child health, statistics, sanitation, bacteriology, nutrition, and mental hygiene, but also business man-

agement, economics, sociology, and administration, are part of in-service training. In-service training is a big thing. In-service training is many little things.

In Mississippi all of these methods of in-service training are known, valued, and used. One of the important factors in personnel training in Mississippi has been the development of a training center at the Lauderdale County Health Department. This center is partially financed by the Commonwealth Fund in the interest of better public health personnel in Mississippi. On October 1, 1939, the school opened with organized courses of three months in practical public health for health officers and nurses.

Courses for sanitation supervisors got under way in July, 1941. The clerical training program started in January, 1943, and organized venereal disease investigator courses in recent months. At present classes are conducted for clerical workers and venereal disease investigators only. Resumption of formal training for health officers, public health nurses, and sanitation supervisors is mandatory, with a priority claim on the excellent staff members coming back from military service.

From October 1, 1939, to June 30, 1943, 40 physicians, 84 nurses, and 18 sanitation supervisors received training at the Lauderdale County Center.

Nurse training was under the direction of the supervisor and assistant supervisor of nurses. One to six trainees at a time were given training, and carried on a program of classes and planned field work. Each trainee was assigned to a staff nurse. She had her desk adjacent to that of the staff nurse and she and the staff nurse worked together in the office and in the field during the first two months of training. During the last month the trainee was given more responsibility and allowed to work alone, though with guidance.

Health officers and sanitarians had similar experiences in formal training and supervised field work. Each acted in the capacity of an assistant. Joint classes were held for health officers, sanitarians, and nurses in order that they might see the broad picture of public health and the value of dovetailing their services.

How valuable to the sanitation program can be the public health nurse who, finding an expectant mother drinking from a contaminated water supply, an infant suffering from diarrhea and covered with flies from an insanitary privy, reports these findings to her fellow workers, the sanitarians!

It is encouraging that unusually good clerks have been maintained in Mississippi throughout the war emergency. The quality of personnel dropped less in this field than in any other relating to public health. This has probably been due to the fact that these jobs were filled for the most part by high-type, home-town girls who preferred the stability of a job at home to war-time inflation and inconveniences in other places.

The clerical training program in Mississippi is a 4 weeks' course designed to cover every phase of clerical activities in a county health department. Following this 4 week period of training in Lauderdale County, the clerk comes to the central offices of the State Board of Health in Jackson to observe the functionings of the various divisions. During the absence of the clerk-trainee from her county, a substitute clerk carries on her routine duties.

The clerical training program is sponsored by the Commonwealth Fund and set up on a special budget. The budget provides for an instructor, two substitute clerks, and funds for paying travel and subsistence for trainees. Trainees are selected from clerks who have had considerable experience in a county health department, because such persons

can absorb more of the details connected with clerical duties than new employees.

A number of central office clerks have been assigned to the clerical training center for a period of 2 weeks. During this accelerated course they are better able to appreciate the functionings of a local health department, particularly its clerical duties. From January 1, 1943, through June, 1945, 42 county health department clerks and 7 central office clerks received clerical training.

The venereal disease investigator receives at the center 2 weeks of intensive training following a short period of orientation in his county. After he returns to the county, a supervising venereal disease investigator works with him there immediately to help him with actual field problems as they arise.

Though exigencies of war shook to its foundations the formal training center program for health officers, nurses, and sanitarians, throughout the war valuable training was carried to the public health staff members in the form of county staff meetings, regional institutes, and state meetings. The subject of venereal disease has been one about which a great deal of staff education has been necessary in order to keep up with the new methods of treatment.

During the past year five 1 day regional conferences were held for public health nurses, three 1 day district conferences with health officers, and one 2 day state conference for venereal disease investigators. The purpose of all of these conferences was to bring out the new emphases in the venereal diseases—selection of patients for treatment centers, follow-up on treatment center patients, and renewed efforts in the epidemiology and diagnosis of venereal diseases. Now that the tremendous clinic load has been removed from county health departments—loads running up to 600 and 700 patients per clinic—the health department has

regained its primary function in quick and accurate attention to contact, follow-up, and diagnosis. In investigator, health officer, and nursing conferences a formal presentation in syphilis and gonorrhea facts was given, followed by round table discussion and questions.

After these venereal disease conferences the state supervisor of venereal disease control conducted a full staff conference in each local health department going thoroughly into the findings of the venereal disease survey previously conducted and the way the problem was being met in each county. Complete redirection of the venereal disease program was brought about with a remarkable amount of coöperation and understanding because of the in-service training given through these regional conferences.

A further interesting development in the venereal disease program in Mississippi has been the establishment of the first State Fever Therapy Unit supported by legislative appropriation. Under the direction of Dr. H. Worley Kendell, ten nurses have been given training in hyperthermy treatment and physiology.

Mississippi's program of training newcomers in the public health family—health educators—has got off to a good start. Demand for health educators in the state has been very much in excess of the supply available through normal channels. Recognizing the fact that the State Board of Health had to "grow its own," a project to seek outside aid for this purpose was sponsored jointly with the State Department of Education and the Delta Council, potent regional chamber of commerce. The General Education Board, joint sponsor with the International Health Division of the Rockefeller Foundation of Mississippi's coördinated school health project, agreed to back financially the program of training health educators over a span of several years.

Careful recruitment has made possible a wise selection of trainees with intellectual leadership, emotional maturity, and a background in teaching or other public service fields. At present eight such individuals are in schools of public health securing graduate work leading to either a Master's Degree in Public Health or a Ph.D. with public health emphasis. Three of these individuals are Negroes. In addition, one health education trainee is being financed by maternal and child health funds, and another by tuberculosis funds. Health educators at work have been trained through funds from the Commonwealth Fund, Kellogg Foundation, U. S. Public Health Service (Tuberculosis), U. S. Public Health Service (Venereal Disease), and U. S. Public Health Service. (Title VI).

An experiment in short-range in-service training of teachers which has met with decided success has been tried in Mississippi during the past two years. Carefully selected teachers who were well known and highly regarded in their counties were brought to Jackson and given a 2 week course in the fundamentals of public health, with particular reference to maternal and child health.

Given definite and specific instructions in organization, how to work up immunization conferences, tuberculosis clinics, maternal and child health conferences, these educators were able to increase attendance at already scheduled conferences and clinics, thus making the professional time going into medical and nursing conferences more far-reaching. Each summer educators attained proficiency in teaching the simple facts about a few of the major fields of public health and greatly increased the understanding of those attending conferences and clinics through personal and group teaching in such fields as nutrition, mouth health, and tuberculosis.

Although not paid during the school

term by the local health departments in which they worked, these teachers, because of in-service training and experience they received, are carrying the message to Garcia in strategic ways throughout the year.

The initiation of the extended program in malaria control and DDT dusting in fourteen counties of Mississippi led to staff education in this field. A 2 day institute was held for Malaria Control in War Areas personnel to acquaint them with the program and to demonstrate spraying techniques. The excellent educational facilities of Malaria Control in War Areas offices in Atlanta were used in staff education on malaria of four health educators, two entomologists and one engineer. Two engineers, one educator, and one entomologist took special work in typhus control and DDT dusting at Malaria Control in War Areas offices in Savannah, Georgia.

Summer health educators working in counties having the extended malaria control program were held over three extra days following their 2 weeks' orientation course for special instruction in entomology, parasitology, and in the medical and engineering aspects of malaria control.

Numerous postgraduate courses for physicians have been given in Mississippi during recent years. Mississippi physicians have attended pediatrics and obstetrics courses at Tulane School of Medicine, Saluda, North Carolina, Harvard Medical School, and Slossfield Health Center at Birmingham, Ala. In March, 1945, five 1 day wartime courses in pediatrics and obstetrics were held with the cooperation of the Tulane School of Medicine throughout Mississippi. These were enthusiastically received by busy general practitioners.

In March, 1945, Dr. P. S. Pelouze of the University of Pennsylvania Medical School held fourteen special meetings of medical societies in Mississippi, speaking on the diagnosis and modern

management of gonorrhea. These were attended by 65 per cent of the physicians of the state.

For many years a program in medical education has been carried on through cooperation with the state and local medical societies, State Board of Health, Tulane University School of Medicine, and other medical leaders.

Of value also in a constant program of in-service training is the planned staff conference, both local and state. Since 1939 the State Board of Health has had regular staff conferences for central office staff members. In the democratic way a committee of staff members plans these conferences each year for twelve months in advance. Conferences usually last an hour and a half and are held every three weeks on Saturday mornings when field workers are in.

Staff conferences for 1944 included the following:

- Jan. 8 Periodic Health Examination
Dr. Felix J. Underwood
Dr. D. V. Galloway
Dr. A. L. Gray
- Jan. 29 War Neuroses
Col. J. M. Cotton
- Feb. 12 Mississippi's EMIC Program
Dr. Virginia Howard
- Mar. 4 Public Health and Social Welfare Relationships
Dr. W. G. Hollister
Miss Sara P. Ricks
Miss Marie Hoffmann
- Apr. 1 Control of Tuberculosis among Negroes
Dr. Henry Boswell
- Apr. 22 How the Army Rehabilitation Program Can Be Used to Train New Public Health Personnel
Dr. J. A. Milne
- Apr. 22 How the Laboratory Can Protect Citizens of Mississippi Against the Post-war Spread of Disease
Dr. H. C. Ricks
- Apr. 22 Communicable Diseases After the War
Dr. A. L. Gray
- June 3 Youth Problems in Wartime
Mrs. T. Grafton Abbott
- July 1 Mississippi State Board of Health Meeting
Dr. Felix J. Underwood

- Aug. 3 The School Health Service
The Division's staff
- Sept. 23 Milk in Mississippi
Dr. N. M. Parker
- Oct. 21 American Public Health Assn. Meeting—A Review
Various staff members
- Nov. 18 A Year in Child Guidance
Child Guidance Staff
- Dec. 30 A New Public Health Year
Dr. Felix J. Underwood

Participants, while mostly health department personnel, may come from related fields and other agencies.

Planned staff conferences are held in a number of the county health departments. An example follows:

- Aug. 17 Venereal Disease. Case finding
Program and Investigation.
Educational Aspects
Mr. A. W. Comings
Miss Cassie Smith
- Sept. 7 Venereal Disease. Laboratory Contributions
Mrs. Katie W. Field
- Sept. 21 Malaria. Problem and Recommendations for County.
- Oct. 5 Disease Carried through Food, Water, Milk and Improper Sewage Disposal. Problems of County and Recommendations.
Mr. Keith Smith
- Oct. 19 Dental Hygiene
Mrs. Lucile Pitchford
- Nov. 2 Mental Hygiene.
- Nov. 23 Tuberculosis, Stage, Chances for Cure of Each Stage. Case Finding Program in the County. Recommendations.
Mrs Dorothy Myers
- Dec. 7 Health in Religion.
Dr. R. C. Bourret

The medical and public health library of the Mississippi State Board of

Health has been of tremendous significance in keeping public health workers in the state on their tiptoes. With its 6,200 volumes and numerous current journals, the library serves the needs not only of public health workers—health officers, public health nurses, dental hygienists, engineers, sanitarians, health educators, and others—but physicians, dentists, nurses, laboratory technicians, and the like who are concerned with individual and community health.

Recognizing that in that Utopia "when things get back to normal" a full-time 12 month course in public health is the desideratum for the majority of public health employees, public health leaders are recommending an enlargement and improvement of existing public health schools, and perhaps the establishment of additional public health schools to meet the need for trained workers. It is even possible when Mississippi has its own 4 year medical school that there might well be in connection with it a department or school of public health.

Certainly for the field which is the leader in health protection programs, the most carefully selected and best trained people are none too good. Where excellence can be learned we must teach it. Where it can be cultivated we must tend it. Public health has come of age. Its youth has been so creditable that it is destined to assume health leadership in increasing amounts as time goes on.

New Virginia Communicable Disease Control Manual

The Department of Health of Virginia, of which Dr. I. S. Riggins is the Commissioner, is rewriting its *Communicable Disease Control Manual*. The new *Manual* is being patterned after the recommendations of the As-

sociation's 6th edition of *The Control of Communicable Diseases*. Dr. Henry H. Henderson, Virginia State Epidemiologist, will supervise the preparation of the revised manual.

Health Education

LAWRENCE K. FRANK

Director, Caroline Zachry Institute of Human Development, New York, N. Y.

EVERY society has had some kind of health education, usually expressed in proverbs and folklore and the teachings of its religion. These beliefs and practices are passed on to each generation of children and youth as the distilled wisdom of the past to guide their living and help them to escape the misfortunes and illnesses to which the group may be exposed.

Health education programs usually start with a body of knowledge about diseases and human functioning which constitutes the subject matter of their programs. This basic scientific and clinical material is then organized into a systematic course of instruction like other subject matter, such as geography or biology or physics and chemistry.

While this method of approach is in accord with prevailing educational theory and practices, and is being supplemented by visual and other aids, it largely fails to recognize the traditional beliefs and practices, with respect to illness and health and the very personal, emotional character of health.

From different studies, it has become clear that early in childhood the individual begins to develop an image of his or her own body and a way of feeling about bodily functions which usually persist, as the individual's characteristic mode of adult thinking, acting, and feeling toward all questions concerning his or her own body and its functioning.

Eating is subject to a variety of parental practices which have large significance for the infant and his subsequent attitudes and feelings about food. Some babies, especially those

who are breast fed, on a self demand basis, may develop a feeling of enjoyment of eating which makes eating an occasion for gratification. Other babies, compelled to accept a rigid feeding schedule which may ignore their individual needs and subject them to prolonged hunger, may develop strong feelings about food and eating which continue to operate, especially if reinforced by difficult weaning and "forced feeding." These babies may never develop a feeling of enjoyment toward eating, but rather they may learn to resist food, especially when the parents try to force them to eat. Some may learn to use food as a weapon to coerce their parents, refusing to eat unless they are cajoled and bribed, while others use food and digestion to fight their parents.

Thus eating may become affected with a variety of feelings and serve as a form of parent-child conflicts, as shown by the many feeding problems among preschool children, the finicky appetite among school children, and the food aversions among adolescents. What should be a normal physiological process of eating and enjoying food thus may be loaded with all manner of emotional conflicts and moral issues. Later on these persistent feelings about eating and the traditional food habits the child has learned in the family may operate to defeat the health and nutritional programs designed to foster better nutrition.

Eliminations likewise often become the focus of parent-child conflicts over "toilet training," especially when at-

tempted too early or too rigorously. Thus, the process of eliminating may become an occasion for anxiety and guilt that persistently interferes with normal regular functioning.

Too many children are punished by being deprived of food or by being subjected to physical pain, as in spanking or beating. This may create a feeling about his body as a source of pain and unhappiness. It is not infrequent for parents to tie a child's hands and otherwise attempt to block and to punish him severely for infantile masturbation. Thumb sucking also may be rigorously opposed by various methods of restraint and physical punishment.

Sleeping is another process which may become a persistent focus of emotional conflict over the parental practices of enforced naps, keeping the child in bed as a punishment, and similar use of a physiological function for disciplining the child.

The emotional reactions of the child that we call anger and rage also are basic physiological processes which parental training often warps and distorts into persistent reaction patterns such as resentment against adult authority. Frequently the naive impulsive emotional response which is quite appropriate to an infant or young child is so strongly punished that the child learns to repress any overt expression of his feelings, which thereafter he releases in various disturbed functions—digestion, eliminations, breathing, etc., and in fantasies or disguised and surreptitious rebellion.

All these practices of infant and early child care and rearing develop in the child a way of feeling about his own body and its various parts, reactions, and functions. He may feel at ease and be at peace with himself or he may develop strong feelings of anxiety or of guilt over bodily functions and of resentment against adults who make him unhappy by these often unnecessary

deprivations, frustrations, coercions, and painful punishments. These feelings tend to persist as the individual's characteristic way of feeling about himself, and they give rise to his image of his own body.

Often the child's image of his own body is influenced by the not infrequent parental teachings that the human body is shameful and indecent, to be kept hidden and ignored or even despised as unclean or dirty. Anything below the neck is to be covered up and tacitly denied, not pleasant or nice or as a source of wickedness and evil.

The persistence of this traditional attitude toward the human body is of large significance for medicine and for health education because it operates in so many ways to defeat what health education is attempting to achieve. It also appears in what many people believe and do about illness and their refusal to utilize available medical services for their own personal care. It must not be forgotten that illness has long been considered by some groups as a visitation or punishment for an individual's wickedness or failure to perform piously his religious duties. These convictions are reinforced by the traditional belief about the human body, which may then become the source of lifelong emotional resistance against not only health education but also needed medical care as well.

Another influence in the life of the young child which may establish persistent attitudes and feelings toward health education is the contacts with physicians and nurses. We forget that the young child may be seriously and permanently antagonized in his often painful experiences with physicians, such as immunization, vaccination, and inoculation.* When the child is seri-

* It has been proposed that the routine injections be given by someone the child will not again see or be treated by so that he will develop confidence in the physician and nurse who care for him, or that local anesthetics be used on children.

ously ill and suffers pain, as with coughs, ear conditions and similar localized infections, he may develop a feeling that anything to do with illness or health care is unpleasant and to be avoided so far as possible. These reactions are not inevitable, however, because some children who have been prepared for these experiences and who have been handled patiently and gently, do not develop these emotional reactions to physicians and these attitudes toward illness and health. But, for the bulk of children, it is safe to say that their early experiences with physicians and nurses, like their early experiences with dentists, is usually painful and disturbing and productive of persistent anxiety toward their own bodies and of resistance or hostility toward those upon whom they may have to depend for care.

During adolescence the individual boy or girl is again exposed to a number of experiences which may further contribute to his or her attitude toward health and feelings about bodily processes. While some adolescents grow, develop, and mature with relatively little disturbance or strain, a considerable number of adolescent boys and girls undergo a prolonged period of physiological instability as they grow rapidly in stature while their various organ systems and functional capacities lag behind. Thus, these adolescents are sometimes compelled to live for two or three years on different levels of maturity, with all the incoördination, clumsiness, and instability which this uneven growth and development entails. Such boys and girls may become exceedingly sensitive about their own bodies and worried over their functional capacities: the girls especially may be emotionally disturbed over the beginning of menstruation, particularly when it may require one or two years before they attain any degree of normal menstrual regularity.

It should be remembered that during adolescence the growing boy and girl have to become accustomed to their changing bodies and how to live with the new functions, impulses, and sensitivities that come with sexual maturation. Also they are expected to clarify and accept the masculine or feminine rôles and ways to act and feel as a man or woman in our culture.

There is also a reluctance to accept adult advice and guidance, often a strong resistance against the various programs of hygiene, health education, and physical training. These programs, however well meant, often arouse greater anxiety in boys and girls who are worried about their normality and preoccupied with the extraordinary beliefs about the human body and its functions, derived from their childhood experiences and from adolescent folklore.

The scientific knowledge and good advice offered in the courses in hygiene and health education are therefore often rejected and treated with horseplay because they cannot be emotionally accepted or reconciled with these preconceptions and anxieties.

The experiences of the young child and the adolescent must be recognized as playing a considerable rôle in the readiness of individuals to accept and to be guided by various forms of health education both at home and in the schools.

It may be appropriate here to point out how much of the sex education we offer youth is apparently designed to frighten and terrorize young people by picturing the horrors of venereal disease and the wickedness of prostitution. Neither of these is very helpful to young people who are struggling to find some way of understanding the place and function of sex in human living, handicapped by the deliberately misleading ideas given them in early childhood. Nor does the elaborate teaching of the processes of gestation

provide much guidance to adolescents who are not interested in having babies but in trying to find out what to do and say to members of the other sex and how to translate sex into love in accordance with our traditional aspirations.

When one looks at the large picture of health education and especially at what is being attempted among adults, it is evident that much of the present endeavor is ineffective because it does not recognize these personal attitudes and emotional reactions of individuals toward their own bodies and these traditional beliefs about the whole subject of health. While it is customary to speak of the instinct of self-preservation, and to assume that each individual is eager to enjoy health, or at least freedom from illness, it must not be forgotten that individuals also are resistant to changes in their ideas and living habits. They will change only when they can emotionally accept new beliefs and practices as psychologically equivalent to their old habits and expressive of their cherished values. It is also clear that the most difficult and baffling aspect of health education is this intangible but potent attitude of the individual toward himself or herself. Not infrequently men and women may vigorously reject what they may urgently need in the way of medical advice and treatment because they have no respect for their own bodies and feel they are not worthy of such help.

A recognition of these attitudes and emotional reactions toward illness and health is essential if health education is to become more effective in the life of the individual. There are innumerable beliefs and practices about health and medicine derived from the past which persist as folklore and customary practices in the lives of individuals, especially in the United States, because we are made up of representatives of so many different nationalities, each with its traditions to which they loyally

adhere. These beliefs and practices enjoy all the sanction of immemorial tradition, and they may persist in the face of the most vigorous programs of health education and despite repeated treatment by scientific medicine.

If health education were approached as a problem of epidemiology, it would be appropriate to start, *not* primarily with the scientific knowledge to be taught, but with the discovery and delineation of the ideas, beliefs, and feelings about human functioning, health and illness which constitute the basic patterns of different groups in the population. This would mean studying the existing beliefs and living habits of different groups of people in each community to reveal their cultural traditions, that vary according to ethnic, national backgrounds, religious affiliations, and other groupings. These traditional ideas and living habits constitute the social, cultural environment in which people live, and offer the major obstacles and resistances to health education and to medical care. Health education, therefore, may be conceived as a process primarily of changing these cultural traditions by which people live, just as much as public health is changing the geographical-biological environment. This means providing emotionally acceptable equivalents based on scientific knowledge for the older beliefs and practices that must be replaced, if people are to understand and accept the new knowledge essential for their health.

A comprehensive program for health education would endeavor to focus the growing knowledge of human functioning and what is necessary and desirable in the maintenance of health for each stage in the life career of the individual, to be transmitted by those who are in a strategic position to influence the thinking and action of individuals in each of those stages. Thus, health education would increasingly develop preconcep-

tual preparation for child bearing since it is becoming evident that the physiological, nutritional, and emotional readiness of the woman for pregnancy plays a large rôle in the development of the unborn child and in child bearing. This means that any attempt to reach women for preconceptual preparation must be addressed to the adolescent girl, through high schools and colleges, in order to give her an understanding of her own functional needs and capacities and a realization of how she can better prepare herself for pregnancy, thereby protecting herself and favoring the development of her child. Here it would be necessary to study the folklore that circulates among adolescent girls, and the many unfounded beliefs and practices of personal hygiene which make health education of adolescent girls a difficult task. Moreover, it would be necessary to recognize the strong emotional reactions among adolescent girls over their female organism and functional processes, including their acute anxieties, their feelings of guilt, and their frequent resentment at being a woman in a "man's world."

An attempt to reach adolescent girls and young women with such a program is especially important because the further reduction of maternal mortality and of pregnancy wastage, that is, of spontaneous abortions, prematurely born infants and stillbirths, seems feasible only through better understanding and more active collaboration by women themselves for their own protection during pregnancy.

The task of health education is also to devise more effective methods of guiding mothers in the care of infants and young children since what they do and what they fail to do is so largely controlling over the child's physical and mental health. Much more can be done in the education of young women during high school and college years when

the new understanding of child growth and development and of early personality formation can be presented as part of their general education. At present those engaged in advising young mothers are so often discouraged by the complete lack of even the most simple understanding and the inability to accept and utilize what pediatrics and well baby clinics and mental hygiene teachings have to offer. The persistence of older ideas about babies and children negates much of the teachings in well baby clinics and infant hygiene stations.

The various professional groups concerned with women, children, and the family must themselves receive further education and training if they are to contribute to this larger task. When physicians and nurses and social workers learn to intercommunicate and are better prepared for parent education, they can translate new knowledge and understanding and insights through their usual professional contacts. It is essential that these different professions integrate their teachings to avoid confusing women with conflicting ideas and advice, as at present.

Health education must be recognized and accepted as a vitally important element in the total educational program, at least of equal significance with the training in various skills and the acquisition of various academic subject matters.

It cannot be too strongly emphasized that the aim and purpose of health education is to help the individual student to reorganize his ideas, his thinking, his image of his own body, and, above all, his feelings and conduct, especially in his living habits, so that the conservation of his health becomes incorporated into his daily thinking, living, and feeling. The aim of health education should be to reorient the individual's attitudes and feelings toward his own body and its functions and needs: to give him the

new understanding and conceptions which he can use in place of the many obsolete, even archaic, beliefs about human functioning and living, to inform him about desirable health practices and health resources; and, above all, to create the feelings which are basic to individual health care and more intelligent living.

It may be urged that an effective program of health education must be at the same time an effective program for the development of better mental health among students at all ages. In many cases the most desirable and effective approach to the student may not be through direct presentation of materials dealing with health, but rather by a variety of experiences which will modify and change some of his basic assumptions and beliefs and feeling tones about life in general and himself in particular.

When so approached, it becomes clear that for different students, different subject matter courses and school experiences may be most influential in redirecting their thinking and feeling and living habits. Thus, some students may gain illumination through the course in literature, others through the work in biology or even in the physical sciences, chemistry, and physics; other students may be more susceptible to materials and experiences that are presented in social studies and social sciences, and others in art work or dramatics or home economics. In addition to these generally recognized courses, it must be remembered that increasingly the schools must provide a variety of special courses and planned activities, especially for students coming from certain family backgrounds, who need help and guidance in such elementary activities as personal cleanliness and grooming.

A well considered program of health education will make better use of the many opportunities offered by the

schools and colleges through school luncheons, cafeterias, physical education, organized athletics, and whatever form of counselling and guidance may be provided for individual students. Perhaps the major difficulty today is the frequent lack of a clearly formulated program through which these diverse activities and specialized personnel can be articulated into a more coherent and effective program of health education for students. Too often each teacher counsellor and administrator pursues his or her own program with little concern for what others may be doing and with little or no realization of how difficult it may be for the student to reconcile and integrate these diverse programs and conflicting advice.

A threshold task for health educators is to formulate a broader, more comprehensive conception of what is essential so that in the planning of the total curriculum, in the establishment of the educational programs, and in whatever is done to and for the individual student, the objective of health education is explicitly recognized and effectively provided for. When so approached, it will be found that many of the existing courses in the elementary, and in secondary schools especially, may need considerable reorganization and reorientation so that they will be more nearly addressed to the understanding and the needs of individual students at different stages of development and made more relevant to what children and adolescents are really interested in and want to know.

Health education, however, is not limited to the formal educational programs of our schools and colleges. There is an immense amount of time, energy, and money spent on health education programs addressed primarily to adults, approached through lectures, radio programs, and a wide variety of printed materials of varying degrees of effectiveness. At the present time the

organization and operation of these many programs of health education are conducted by different organizations, each of which has selected for its major emphasis some one or more of the major threats to individual health or needs for healthful living. Thus, there are specialized and independent organizations and programs concerned with tuberculosis, infantile paralysis, with cancer, with diseases of the heart and circulation, with diabetes, with rheumatic fever, with venereal disease; also nutrition and care of teeth, eyes, ears, preparation for pregnancy and child bearing, and so on.* It is becoming clear that this fractionation of health education, while offering certain advantages of specificity, at the same time suffers from the inevitable confusion which these separate programs create in the mind of the public.

At present, health education is aimed at families and individuals in the endeavor to persuade or compel them by various appeals, rational, intellectual, expository, promise of personal gains and advantages, fear of disease or death, or authoritarian pronouncements, to accept what is offered. To a large extent, it is a mass program designed to change individuals, using various motivations and selected bodies of new knowledge, to influence individual decision and action. But the arguments used, the threats and the promises made, and the invocation of science are both psychologically and socially of questionable validity and of little effectiveness.

This diversity of programs warrants more careful study and reflection because in addition to the many privately supported agencies, there are many governmental organizations on the federal, state, and local levels also engaged in conducting different programs of

health education. Sooner or later there must be some resolution of the existing divergencies through the development of generalized methods and practices that can and should be utilized by all engaged in health education.

All the different endeavors are focused on the same basic problem, namely, of persuading families and individuals to modify their living habits in the light of new knowledge and new resources for meeting these persistent life tasks.

There is need for some larger strategy to guide all these different efforts and some more effective techniques for approaching individuals and families and persuading them to alter their customary living habits. In such a larger strategy, health education would take its place as one, but only one, of the objectives to be pursued along with all the other efforts to improve human living. Such a correlation of programs will not occur, however, until each of the various organizations conducting these diverse programs recognizes that it is part of this larger endeavor and realizes that its specific efforts, whether for health or nutrition or child welfare, mental hygiene, or any other objective, can be effectively sought only through this coordinated approach.

In addition to these programs conducted by public and private organizations, there are the innumerable commercial programs which offer advice and often give specific instructions about health and care of illness. Thus, in the advertisements of various drugs and medical preparations and foodstuffs, the public is being told what to believe and what to do about health needs, and how to diagnose and treat illness and impaired functions. The radio commercials especially are aimed at the family and the individual and often create further confusion and conflict in people's beliefs and practices by what

* U. S. GOVERNMENT PRINTING OFFICE: 1935

they so insistently urge. Not infrequently these commercial programs are lacking in validity, and deliberately play upon the anxieties of people for selling some health food or patent medicine.

The responsibility of individual physicians for the development of health education should also be recognized here. Unfortunately, the contacts of patients with physicians rarely serve as educational experience for the patient, because the doctor is either too busy to offer any explanation and advice beyond the specific instructions for the illness or disease he is treating or he is not interested in trying to modify living habits of patients. Moreover, many physicians are convinced that nothing will change people's ideas and living habits because they are too "dumb" or indifferent. Every physician is faced with this baffling problem of how to communicate his knowledge and his judgment of the individual patient in such a way that it will be accepted by the individual and will be utilized in guiding his daily living. Even when the patient may be in a highly precarious condition which will become more threatening unless he modifies his customary practices of eating, drinking, smoking, sleeping, working, playing, and so on, he may still be resistant to any medical advice and unable or unwilling to modify these customary living habits. When it is realized that each individual develops a way of life which he can change only when helped with skillful guidance and the reinforcement of someone he trusts and admires, it will become obvious why the customary didactic advice to patients is of so little avail. For many individuals any effective alteration in their way of life calls for something equivalent to psychotherapy since they can change their mode of living only in so far as it is accompanied by some alteration in their personal orientation and their

profound feelings toward life. Group therapy may provide an effective procedure, as already being used with diabetics and neurotics.

Perhaps the most fruitful opportunity for health education of the individual patient is in the period of convalescence when he may be more susceptible to guidance and redirection because he is recovering from an illness and may be emotionally more receptive to such advice.*

As more and better provision is made for convalescent care, the opportunities for this health education will be increased. Full advantages of such opportunities will, however, not be taken unless there is a clear realization of the kind of reëducation and psychotherapy that is needed to be effective with different patients. Recent experiments in the development of group methods indicate that individuals with much the same ills and needs can be effectively helped through group discussions and group decisions. It has been found that the association in a group with common needs and difficulties may be utilized as a very potent influence upon the individual to modify his customary patterns of thinking and feeling and living.

As organizations are established for the provision of medical care under different auspices, the need for better health education will become more urgent. Those enrolled under such plans usually have little understanding of how to make intelligent use of and to get full benefit from the medical services to which they are entitled. Many individuals also are inclined to make unnecessary demands upon the medical services made available through prepaid plans, thereby adding to the cost and interfering with the effectiveness of the organization. A systematic effort to reëducate members of such

* New York Academy of Medicine, 1944 Conference on Convalescence and Rehabilitation.

medical care organizations must be undertaken as a necessary step in the further development of prepaid medical care and of preventive medicine to keep people well.

The protection and the guidance of the individual to meet the sequential changes in living as he grows older will soon become one of our major health problems because of the rapid growth of the population over fifty, among whom there is now so much chronic illness, disability, and impairment, and psychosomatic disorders. Organizations for medical and health care should become the major agencies for health education, just as the family doctor in previous generations advised and cared for individuals from childhood on.

To a considerable extent health education and medical services have been provided on the assumption that each individual was relatively free to develop whatever design of living he might prefer and to jeopardize his health and functional efficiency to whatever extent he might wish. Health education has endeavored to persuade each individual to modify the use of this freedom, while medical services have endeavored to provide such care and treatment as he may require if he develops an acute illness or otherwise has impaired his functional capacities by his customary way of life.

With the development of programs of health supervision and medical care in the armed forces, with the rise of organized efforts in industry to provide health supervision and with the development of various forms of health and medical care in educational institutions and of prepaid medical care in communities, we may be undergoing a significant modification of this historic conception of individual freedom and responsibility with respect to health.

While there is no immediate prospect of any such movement, it is possible that in the years ahead there may be

a growing acceptance of the principle that the individual is not at liberty to endanger his life and to jeopardize his health, because he is a responsible, participating member in a social order, whose carelessness or perversity in regard to health is a threat to the integrity of that social order. The development within recent years of programs designed to discover those who have been exposed to tuberculosis and venereal disease and to compel them, if necessary, to submit to treatment, should be considered as one possible indication of this future trend. Likewise, the commitment of those with mental disorders offers another indication. Reference should also be made to the growing requirements of vaccination for smallpox and of various forms of immunization, for example, diphtheria, which are required of all children seeking admission to the public schools. Further indications of this movement are to be seen in the progressive expansion of public health controls which are being exercised over an increasing range of individual and organized activities where either the individual himself or the community may be threatened by what he does or fails to do.

To the extent that the causes or sources of illness are understood, it is probable that our historic attitude toward the sick may undergo a considerable modification. Instead of thinking of the individual who is ill as unfortunate, it is likely that for many forms of illness and disability and impairment, the individual will be considered to have been grossly negligent and careless or unintelligent, as suggested in Samuel Butler's *Erewhon*, years ago. It is illuminating to regard the changes that have taken place in the conception of accidents and their prevention during the past thirty or forty years, bringing a clearer recognition of how often an "accident" is not unrelated to the per-

sonality of the one injured and to various controllable factors in the environment.

These speculations about the future are not irrelevant to the tasks of health education today because sooner or later those engaged in health education must clarify the basic assumptions upon

which they will proceed, and endeavor to formulate some kind of social philosophy and concerted plans of operation that will more effectively translate new knowledge into living habits and will guide our whole social order in the interest of health care and human conservation.

Know Your Public Health Nurse Week

President Truman paid tribute to the more than 20,000 public health nurses of the nation in a message in connection with the first annual observance of Know Your Public Health Nurse Week, April 7-13. Know Your Public Health Nurse Week is sponsored by the National Organization for Public Health Nursing with the coöperation of the U. S. Public Health Service.

The President's message follows:

The Observance of "Know Your Public Health Nurse Week" brings long overdue public recognition to one of the most important groups of health workers in the country. I am pleased that this annual tribute has been inaugurated at a time when our people are awakening to the necessity for a greatly expanded public health program.

If we are to attain "health security for all, regardless of residence, station or race—everywhere in the United States," as requested in the recent health message to the Congress, we shall need not only more medical facilities,

but also more doctors, scientists, dentists, nurses, and other specialists. Adequate public health nursing service for all will require around 65,000 public health nurses—or more than two new nurses in addition to every one now on duty in local, state, and federal agencies.

There is scarcely any public health activity in which the services of the specially trained nurse are not utilized. Her skills complement those of the family physician when she carries out his instructions for home care of the patient in a wide variety of situations. Today, when our civilian hospitals report as serious personnel shortages as they experienced during the stringent war years, the stay of patients is being cut to a minimum and follow-up care in the home is of paramount importance.

Thus, the public health nurse is one of the strongest links in the chain of disease prevention and the promotion of good health on the part of both children and adults. Her contribution to better individual and community health cannot be overestimated. It gives me genuine pleasure to pay tribute to the public health nurses of America. I hope the day will not be far distant when their services will be available to the total population.

Infectious Hepatitis— Presumedly Food-borne Outbreak

MARGARET R. READ, M.D., HULDAH BANCROFT, PH.D.,
JAMES A. DOULL, M.D., DR.P.H., F.A.P.H.A., AND
ROBERT F. PARKER, M.D.

*Demonstrator of Medicine; Assistant Professor of Biometrics; Elizabeth Prentiss
Professor of Public Health; and Associate Professor of Medicine; School of
Medicine, Western Reserve University, Cleveland, Ohio*

IT is commonly believed that the hepatitis seen in epidemic proportions in members of the Armed Forces in 1942-1943 was a human infectious disease acquired from human serum used in preparation of the yellow fever vaccine then in use.¹ This belief presupposes that there naturally occurs in man a hepatitis due to a virus which may under certain conditions be present in the serum or plasma. If analogy with other virus diseases is valid, it may be presumed that a group of agents might cause a disease having similar clinical characteristics.² It would seem worth while, therefore, to record each outbreak of what clinically appears to be infectious hepatitis in which the mode of transmission seems reasonably clear even though conclusive evidence as to the viral cause or exact mode of transmission may not be available.

In the late spring of 1944 an outbreak of infectious hepatitis occurred among students at Western Reserve University School of Medicine. The outbreak was explosive, onset dates for all 24 cases falling between May 26 and June 5 (Table 1).

Cases developed in all four classes: 9 in the first year, 7 in each of the second and third years, but only 1 in the fourth year. All patients were members of a single fraternity.

TABLE 1

Day of Onset of Symptoms in 24 Cases

Date	Number of Cases

5.....	1

Early in April, two first year students were hospitalized because of jaundice. These two men were not members of the fraternity and, as far as could be determined, had had only casual contact with the subsequent patients. One case developed in a dental student two months after the principal outbreak, but again history of only very casual contact was obtained. Other than these, no cases were recognized during the year of 1944.

Data relative to the eating habits of members of the fraternity are shown in Table 2. Of 101 members of the fraternity, only 14 men lived in the house and ate all of their meals in the house dining room. Four cases developed in this group, an attack rate of 28.5 per cent. Sixty men regularly ate all or part of their meals at the house but

did not live there. Among these there were 20 cases, an attack rate of 33.3 per cent. The remaining 27 members either ate no meals or only an occasional one at the house. No cases occurred in this group. No cases occurred in students other than members of the fraternity, in spite of close daily contact in classroom and laboratory. These facts would indicate that regular eating at the fraternity dining room was an important factor in determining the risk of attack.

TABLE 2

Relationship of Meals Eaten at Fraternity House to Attack Rate

<i>Frequency of Eating at Fraternity House</i>	<i>Total</i>	<i>Patients</i>	<i>Attack Rate Per cent</i>
Eating regularly			
Resident	14	4	28.5
Non-resident	60	20	33.3
Eating infrequently	20	0	0.0
No meals *	7	0	0.0
All members	101	24	23.8

* March 1 to June 1, 1944.

An analysis of the number of meals eaten at the house revealed both more regular and more frequent eating by the patients than by the nonpatients. Since an incubation period of from 20 to 34 days³ has been reported in experimentally produced infectious hepatitis, a study was made of meals eaten between April 10 and May 15. This showed that the patients on the average ate 47.5 meals out of a possible 84 served, as compared with 25.9 for nonpatients, a ratio of 1.8 to 1. For a period of 3 months prior to the outbreak the ratio for meals eaten by patients to those eaten by nonpatients was the same.

An attempt to select a single day on which the infection might have occurred was disappointing. On no day did all the patients eat all their meals at the house. Considering only lunch and dinner, since the proportion of breakfasts eaten by both patients and non-

patients was relatively small, there were two days, March 8 and 9, on which every patient ate either lunch or dinner or both. On those days, respectively, 28 and 31 of the 77 nonpatients ate neither lunch nor dinner at the house. Infection occurring on these dates seems unlikely in view of the experimental work reported, as an incubation period of 80 days would be much too long.

There were, however, periods of two successive days each on which every patient ate either lunch, dinner, or both on one or the other or both days. These periods were April 27 and 28 and May 9 and 10. On the first of these two periods, the number of nonpatients who ate neither lunch nor dinner was 18, on the latter 31. Thus either of these two periods might have been the days on which infection occurred.

Investigation showed that the kitchen and dining rooms were clean. Left-over food was stored in refrigerators. Pasteurized milk was obtained daily in 2 gallon jugs and kept covered, but not on ice, until serving. All water used came from the regular municipal supply. Inspection showed no evidence of rat infestation.

Unfortunately no record was kept of the food served at individual meals. Consequently no single article of food could be incriminated. A study of the eating habits of the patients and a sample of nonpatients revealed no essential difference. There had been no symptoms of unusual illness on the part of any employees handling food. Nevertheless, evidence points strongly to an epidemic spread through some article or articles of food served in the fraternity dining room.

The clinical picture of the disease was quite uniform in the great majority of the cases. A number of the salient features of the disease are presented in Table 3. In most cases the onset of the disease was insidious. Malaise and general myalgia gradually increased,

TABLE 3
Frequency of Various Clinical Signs in 24 Patients

<i>Clinical Signs</i>	<i>Number in Which Sign Occurred</i>	<i>Remarks</i>
Hyperemia of pharynx	11	Slight to moderate degree. No associated symptoms.
Superficial lymphadenopathy	6	Usually cervical chain only. Generalized in 2.
Enlarged spleen	6	In one case extended 4 cm. below costal margin. Persisted for 4 to 14 days.
Enlarged liver	20	Varied from a barely detectable enlargement to one extending 4 cm. below costal margin. The liver was fairly firm, edge smooth and somewhat rounded. Usually somewhat tender. Persisted for 4 to 14 days.
Bradycardia	22	Lowest pulse rates were 44 to 60.
Leukopenia	16	Below 5,000 WRC's per cu mm. Highest count, 6,350.
Clay colored stools	10	
Albuminuria	12	Slight to moderate.

chilly sensations were noted, and fever appeared which might rise to 38° or 39° C. About half of the men complained of orbital pain at the time of onset. Anorexia appeared early and by the end of 4-7 days had become severe. By this time nausea was present also, and in many cases was associated with almost intractable vomiting. Dark urine was noticed soon after the onset of illness. In a few cases, it was almost the first sign of disease. By the 4th or 5th day the fever had begun to subside, and within a day or two jaundice was evident and this continued to deepen for several days.

By the end of the second week definite improvement was evident in nearly all cases. Appetite returned, epigastric distress subsided, and sometimes a decrease in the depth of jaundice was apparent. Asthenia persisted in most cases for some weeks after the disappearance of all other symptoms or signs of the infection.

Certain features of the illness which these men presented were strongly suggestive of mononucleosis. Although there were no complaints referable to the pharynx, a hyperemia of definitely

abnormal degree was present in half of the patients, and superficial lymphadenopathy was present in one-fourth. Usually this involved only the cervical chain of lymph nodes. In 6 cases the spleen was palpable, in one case extending 4 cm. below the costal margin. In contrast to mononucleosis, the total white blood count was low, a decrease involving chiefly the neutrophilic cells, but usually with a disproportionate increase in cells classed as monocytes, the percentages of which ranged from 7 to 26. The liver was palpable in almost all cases and usually was tender. The icterus index was high in all cases, the highest being 72. The cephalin flocculation test was positive in all cases at some time during the illness. The prothrombin content of the blood was abnormally low in several cases, but no tendency to hemorrhage was observed. Electrocardiograms were made in a number of cases, the findings of which are being reported elsewhere.⁴ Essentially, there was a depression of the amplitude of the T wave, the extent of which bore no relation to the depth of the jaundice.

During the period of the outbreak

7 other members of the fraternity, 5 of whom ate regularly at the house, exhibited symptoms possibly caused by hepatitis. In none was jaundice observed.

COMMENTS

The clinical picture of the disease in these patients was similar in all particulars to that which occurred among military personnel, and to spontaneous outbreaks in civilian populations.

The possibility of spirochetal jaundice was excluded by studies made by Dr. E. E. Ecker. Blood plasma was examined directly in the darkfield for leptospira. Blood and urine was seeded into Schüffner's leptospira medium and inoculated into young (less than 250 gram) guinea pigs. The urine was alkalized before collection for culture and animal inoculation. The sera of several patients were examined in convalescence for the presence of leptospiral agglutinins. All of these examinations were negative.

A notable feature of the principal outbreak was its explosive character, suggesting a limited period of exposure of a large group of men. No relation could be discovered between the outbreak and two previous cases of jaundice occurring in members of the student body, and no secondary cases were recognized in spite of the close classroom association of men early in the disease with presumably susceptible individuals. In the case of the dental student, the contact was at second hand. Evidence points clearly to the fact that this infection was confined to one fraternity and those who ate regularly at this fraternity had a much higher attack rate than did other members. The evidence of marked disturbance of the lymphatic system was unusually great.

No characteristic change in the differential distribution of white cells could be established and no cells having the characteristics of the abnormal ones which appear in infectious mononucleosis were recognized, but a total of 9 (37 per cent) of the patients had lymphadenopathy, either cervical, general superficial, or splenic, and a white blood count which bore some resemblance to that of mononucleosis.

SUMMARY

An outbreak of infectious hepatitis among medical students is described. The outbreak was explosive, involved only members of one fraternity, and primarily those who ate regularly at the fraternity dining table. The cases were not traceable to previous cases, and so far as could be determined led to no secondary cases.

ACKNOWLEDGMENT—It is a pleasure to acknowledge the coöperation of Dr. A. B. Denison, Physician in Charge of the Student Health Service, who put these cases at our disposal for study and greatly aided in the collection of the data.

Pertussis Vaccine Prepared with Phase-I Cultures Grown in Fluid Medium

SOPHIA M. COHEN AND MARY W. WHEELER

*Division of Laboratories and Research, State Department of Health,
Albany, N. Y.*

THE difficulties encountered in the mass preparation of phase-I pertussis vaccine with strains grown on a blood-enriched agar medium are a common experience. Service costs connected with the provision of an adequate and continuous supply of blood and high and apparently unavoidable losses of media and vaccine due to contaminations not only place production expenses at an unreasonable level but also at times may reduce vaccine yields below distribution requirements. The substitution of a fluid medium that does not contain blood and that can be sterilized by heat offers an approach to the solution of these practical problems. Furthermore, vaccine prepared from whole fluid cultures may contain essential soluble antigenic substances not present in the usual pertussis vaccines prepared by suspending in salt-solution cultures grown on human- or sheep-blood agar.

Hornibrook in 1939^{1,2} reported that *Hemophilus pertussis* could readily be grown in a fluid medium in which organic nitrogen, as in amino acids, certain polysaccharides, and organic sulfur were considered the essential ingredients. These were supplied by hydrolyzed casein, soluble starch, and cysteine or glutathione; in addition the formula included only inorganic salts and yeast extract or nicotinic acid. This medium was suggested for pertussis vaccine

preparation,³ but in early trials it was found that modifications were necessary because certain strains of *H. pertussis* grew poorly or not at all, and some alteration in phase-I characters^{4,5} occurred. Recent papers by Wilson,⁶ Farrell and Taylor,⁷ and Verwey and Sage⁸ give revised formulas for the medium and report favorable laboratory data on the antigenicity of fluid-medium vaccines. Extracts of liver or human blood cells furnished accessory growth factors. The present paper describes a medium that does not require the addition of such extracts and its use in the preparation of pertussis vaccine. It also reports results of potency tests of the vaccine in mice by the newer method of intracerebral injection of test cultures.

SELECTION OF FORMULA

The original fluid medium of Hornibrook was compared with various modifications designed by one of us (M.W.W.) to determine the optimum amounts of the inorganic salts, soluble starch, and cysteine hydrochloride required, the effects of the addition of different amounts of copper, iron, manganese, and zinc, of variations in the pH, and of the use of sources of nitrogen other than hydrolyzed casein. Over forty combinations were tried. Two phase-I pertussis strains, Nos. 40103 and 41405, used in routine vac-

cine production⁹ were cultivated for from two to five generations in each medium dispensed to provide a shallow layer with a relatively large surface area. The cultures were incubated at 35° C. for at least 3 days and the amounts of their growth estimated daily by comparing the turbidities with those of a set of Pyrex glass standards^{10, 11} representing concentrations of from 500 million to 10,000 million *H. pertussis* bacilli per ml. Strain No. 40103 was more readily adapted to fluid medium than strain No. 41405. However, with both, increased growth resulted from the addition of suitable amounts of copper and iron sulfates to the medium, but the growth was markedly granular. By decreasing the sodium and calcium chloride content, cultures of uniform turbidity were obtained. Peptic or tryptic digests of casein were not found superior to hydrolyzed casein, "casamino acids," as the source of nitrogen. The medium finally selected differs from Hornibrook's, especially in decreased amounts of sodium and calcium chlorides, in increased content of soluble starch, potassium phosphate, and magnesium chloride, and in the addition of copper and iron. Also it has been found that the cysteine hydrochloride can be added prior to sterilization.

the starch is dissolved and the medium clear. Filter and dispense in 200 ml. amounts in 1 liter Roux bottles. Autoclave at 10 lb. pressure for 15 minutes.

YEAST DIALYZATE

Brewers' yeast (Fleischmann pure dry, type 2019)	500 gm.
Distilled water	800 gm.
Distilled water	2,000 ml.

Make a paste of the yeast with the 800 gm. of water and transfer to a cellophane tube (500-550 mm. length, about 114 mm. diameter, 0.089 wall thickness). Tie each end of the tube with heavy twine, immerse it in the 2,000 ml. of water in such a manner that the liquid cannot spill or seep through the ends of the tube, and adjust its position to give approximate equality of liquid-level inside and outside the tube. Heat at from 78° to 80° C. for 7 hours. Remove the tube and transfer the dialyzate to a bottle. Add 5 ml. of chloroform per liter, stopper with a rubber stopper, and store in the coldroom. This dialyzate is clear, requires no filtration, and remains satisfactory for use even after several months' storage.

Eleven phase-I pertussis strains were cultivated in tubes of the selected fluid medium for four or five successive transfers. Growth was consistently good. The cultures were uniformly turbid or only slightly flocculent. The bacterial counts after 48 or 72 hours' incubation were usually from about 8,000 million to 10,000 million or more bacilli per ml. according to turbidity

FLUID MEDIUM FOR *H. PERTUSSIS*

(Casein hydrolyzate medium with yeast dialyzate)

Casamino acids (Bacto), technical	10 gm
Sodium chloride (A.C.S.)*	2.5 gm.
Monopotassium phosphate, KH_2PO_4 (A.C.S.)	0.5 gm.
Magnesium chloride, $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ (A.C.S.)	0.4 gm.
Starch, soluble, powdered	1.5 gm.
Calcium chloride, CaCl_2 (A.C.S.), 1 per cent solution	1 ml.
Ferrous sulfate, $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ (A.C.S.), 0.5 per cent solution	2 ml.
Copper sulfate, $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ (A.C.S.), 0.05 per cent solution	1 ml.
Cysteine hydrochloride, 1 per cent solution	2.5 ml.
Yeast dialyzate	50 ml.
Distilled water to make	1 kg.

* A product that meets the standards of the American Chemical Society and bears a label giving the analysis.

Dissolve the casamino acids, salt, phosphate, and magnesium chloride in part of the water. Add the remaining ingredients and make up to 1 kg. Adjust pH to 7.2-7.3. Boil until

measurements. In the course of vaccine preparation, direct counts of cultures grown for 72 hours in 1 liter Roux

bottles indicated that the bacterial concentration was, as a rule, from about 10,000 million to 15,000 million bacilli per ml. No significant changes in phase-I morphologic or cultural characters were noted. Typical hemolytic activity was demonstrated when the last transfers were streaked on sheep-blood potato-infusion agar plates, and with ten of the strains agglutination reactions occurred in high dilutions of a phase-I serum. One strain exhibited reduced agglutinative activity after the third transfer.

PREPARATION OF VACCINE

For the preparation of vaccine, strains Nos. 40103 and 41405 were grown separately for 72 hours in the fluid medium dispensed in 200 ml. amounts in 1 liter Roux bottles. The finished vaccine, sterilized by 0.01 per cent of "Merthiolate," contained 10,000 million bacilli per ml., 5,000 million of each strain.

Beginning with a 24 hour culture on potato-infusion rabbit-blood agar,⁹ three successive transfers to tubes containing fluid medium were made and incubated at 34°-36° C. for 24 or 48 hours. After tests for purity and identity, including agglutination with a phase-I serum, medium in bottles to provide seed cultures was inoculated and incubated for 72 hours. From 15 to 20 ml. of pure and typical cultures were dispensed into each vaccine bottle. The bottles were shaken by hand once a day during the 72 hours' incubation. After microscopic examination of stained preparations, the cultures were pooled in 4 liter graduated bottles. An additional microscopic examination was made and sheep-blood potato-infusion agar plates streaked with material from each pool. "Merthiolate" in a 1 per cent solution was added to the pooled vaccine to give a final concentration of 0.01 per cent, and the vaccine was stored in the coldroom. The cultures were usu-

ally nonviable after from 2 to 3 weeks.

When a lot of vaccine consisted of more than one bottle of each strain, a sample from one was counted by the Helber counting-chamber method on the day of harvesting and diluted to contain 10,000 million bacilli per ml. This dilution was then used as a turbidity standard in estimating the bacterial concentration of samples from the remaining bottles. The bacterial count of the vaccine cultures was adjusted to 10,000 million per ml., equal volumes of vaccine of the two strains were pooled, and routine sterility tests for diluted vaccines made.⁹ Tests for viability of the pertussis bacilli were made at this time and again when the vaccine was dispensed into final containers.

POTENCY TESTS OF VACCINE

The immunizing potency of the fluid-medium vaccine for mice was compared with that of the routine material prepared from sheep-blood starch-agar cultures⁹ and of a vaccine prepared in a fluid medium of different composition by another laboratory. Mice were injected subcutaneously or intraperitoneally with vaccine, and the degree of immunity induced was estimated from the survival rate following the injection of live culture. In early tests, the vaccinated and untreated control mice were injected intraperitoneally with live culture suspended in mucin.¹² The number of bacilli in the minimum lethal dose (m.l.d.) of the test culture was 50 million or more, and the test dose for the vaccinated mice 200 or 400 million bacilli, or only about 4 to 8 m.l.d. Although an apparently high degree of protection could be demonstrated by this method, the test was not sufficiently sensitive to determine the relative potencies of different lots of vaccine. Furthermore, microorganisms other than *H. pertussis* were frequently recovered from the peritoneal fluid and heart's blood of the mice that died. In later

tests, live culture suspended in broth was injected intracerebrally.^{13, 14} The results were in general in accord with those of Kendrick who first applied this method to tests of pertussis vaccines.¹⁵ In order to select suitable test cultures, 20 strains of *H. pertussis* were tested for virulence for mice by the intracerebral method. Four proved to be of relatively high virulence. Fatal infection could readily be induced in mice with doses of from 20,000 to 2,000 bacilli or less of the pertussis strains selected for use in the potency tests, and the comparative potencies of different vaccine preparations could be ascertained with test doses for vaccinated mice of from about 250 to 1,000 or more m.l.d.

Immunization—Mice weighing 8–11 gm. were injected subcutaneously at 3 day intervals with 0.1, 0.2, and 0.2 ml. amounts of suitable dilutions of vaccine. In a few tests, the total dosage was given in one injection subcutaneously or intraperitoneally. Ten mice were used for each dose of vaccine or test culture. On the day immunization was begun, a group of mice from the same stock and of the same weights as the mice to be vaccinated were set aside for controls of virulence. A constant total dose of vaccine and varying doses of test culture were used at first. More recently, the doses of vaccine have been varied in order to titrate the amount of vaccine required to protect mice against a given test dose of culture. The total dosage of vaccine for the different groups immunized ranged from 62.5 million to 4,000 million bacilli.

Injection of live culture—Seven days after the last dose of vaccine, all the mice were injected intracerebrally, under ether anesthesia, with live culture. Strain No. 40103, or a heterologous strain, No. 44122, was grown for 24 hours on rabbit-blood potato-infusion agar, suspended in broth, filtered through cotton, and diluted to equal in density a Pyrex glass standard representing 10,000 million bacilli per ml. Further serial dilutions of the culture were made as required. The test doses of culture, from approximately 2 million to 10 million bacilli for the vaccinated mice and from 200 to 20,000 bacilli for the control mice, were injected in 0.04 ml. amounts. The mice were observed for 14 days. In those that succumbed symptoms of encephalitis began to

appear after the 3rd or 4th day. Most of the deaths occurred between the 4th and 8th days. Fatalities before the 3rd day were omitted from the calculations of the titers, since they were usually due to injury at the time of injection. While there were some irregularities in the survival rates, the results were in general regular and could be duplicated in repeated tests. Pure cultures of *H. pertussis* were, in most instances, recovered at autopsy from the brains of the mice that died.

The fluid-medium vaccines, in repeated tests by the intracerebral method, were definitely superior in immunizing activity to the routine phase-I vaccine, control and current lots, prepared from blood-agar cultures when the doses of vaccine had been administered subcutaneously. Irrespective of differences in the schedule of immunization of the mice, in the test strains, or in the test doses of culture, smaller amounts of the fluid-medium products than of the routine material were required to induce a given level of immunity. In one of two tests, in which the mice were immunized by a single intraperitoneal injection, the fluid-medium vaccine appeared to be of higher potency than the routine control; in the other, there was no significant difference between the two types. The results of representative tests are recorded in Table 1.

The fluid-medium vaccine prepared in this laboratory also compared very favorably with the sample of fluid-medium vaccine prepared elsewhere. These tests were made prior to the use of the present method of titration of the protective dose of vaccine. However, both in intraperitoneal tests with mucin and in intracerebral tests against varying doses of culture, the results indicated a greater immunizing potency in the vaccine prepared here.

In agglutinogenic activity in rabbits the fluid-medium vaccines corresponded to or exceeded the routine products.

TABLE 1

Titration of Immunizing Potency for Mice of Pertussis Vaccines Prepared from Blood-agar and Fluid-medium Cultures

Strains Used in Potency Tests							Type of Vaccine Tested					
Date Tested	Number	Virulence-control Mice		Test Dose Vaccinated Mice	Method Used in Immunization			Total Dosage of Vaccine	Blood-agar Medium *		Fluid Medium †	
		Dose Approximate Number of Bacilli	No. Died		Approximate Number of Bacilli	Injections			No. Died	50 Per cent End Point Number of Bacilli ‡	Protective Dose	
				Route		Number	No. Tested	50 Per cent End Point Number of Bacilli			No. Tested	50 Per cent End Point Number of Bacilli

Note: Test cultures injected intracerebrally.

* Lot No. 19 except on 10/26, then lot No. 36.

† Lot No. 28 tested 5/17, 7/13, and 8/30; lot No. 23, 8/27; lot No. 38, 10/26.

‡ Calculated by method of moving averages, the span being 2 (data for adjacent dilutions averaged prior to the interpolation).¹⁰

REACTIONS IN PERSONS

Data on the immunizing value of the whole fluid-culture vaccine in children are not yet available. However, some information has been obtained on the reactions induced. We are indebted to Dr. Edward A. Lane of the Westchester County Department of Health for the following observations:

Ninety-three children (75, 3 years old or less) were immunized with the fluid-medium vaccine; 111 (83, 3 years old or less) received the state routine phase-I product. With few exceptions, each child received a total of 8 ml. of vaccine in three injections at weekly intervals. No reactions were reported in 51 (54.8 per cent) of the children immunized with the fluid-medium vac-

cine or in 46 (41.4 per cent) immunized with routine material. The reactions that did occur, local or systemic, following the administration of either type of vaccine were not severe. There was thus no evidence to suggest a greater toxicity in the fluid-medium vaccine.

SUMMARY AND CONCLUSIONS

A modified fluid medium based on Hornibrook's formula has been developed which provides satisfactory conditions for the cultivation of *Hemophilus pertussis* in the preparation of vaccine. The addition of copper and iron to the medium was found to stimulate growth, and the optimum amounts of these and other ingredients have been established. Accessory

growth factors are furnished by a yeast dialyzate, and the completed medium can be sterilized by heat. It offers definite advantages over the complex blood agar customarily employed, in that vaccine preparation is simplified and the cost of production lowered.

The whole fluid culture vaccine, according to laboratory tests, appears antigenically superior to vaccine prepared from blood-agar cultures. The intracerebral injection of live pertussis culture in mice previously immunized with pertussis vaccine provided a valuable laboratory procedure for gauging the potency of the vaccine.

Child Health Day, 1946, on May 1

It has been announced by the National Boys and Girls Week Committee for the United States that the period April 27 to May 4 will be observed as National Boys and Girls Week, with Child Health Day falling on Wednes-

day, May 1. Information about plans and suggestions for carrying out the program, including a poster and a manual of suggestions, may be obtained free of charge from the committee, 35 East Wacker Drive, Chicago 1, Ill.

The Public Health Nurse in the Department of Health

KATHARINE FAVILLE, R.N., F.A.P.H.A.

Dean, College of Nursing, Wayne University, Detroit, Mich.

THE war period was a hard one for the public health nurses who stayed home for, like everyone else, we felt greatly frustrated by the amount to be done and the reduced staff with which to do it. We have learned some valuable lessons, however, that should point the way to improved service in the future. One benefit accruing to us was the fact that, if the nurse was to cover her work at all, she was forced to think in terms of relative values and to ask herself repeatedly:

What type of visit comes first when I cannot make them all?

How much more can families do for themselves?

How much and what can be taught to groups rather than to individuals?

What am I doing that could be done equally well by volunteers or non-nurse employees? (It is interesting to note in passing that, for the first time in some larger cities, public health nursing services during the war have been able to secure adequate clerical assistance, because nurses were unavailable and clerks a little less so.)

In the light of our war experience, I would like to discuss some of the next steps ahead, and what we must do to utilize to best advantage the increased personnel that we hope will soon be available. One does not have to talk with more than a few of the nurses returning from military service to realize that many of them do not want to return to luxury services—they want to work where they are really needed. If we are to attract them to the public health nursing field and hold them

there, we cannot return to the "good old days," but will have to develop a sharp sense of relative values throughout our entire service.

What of the public health nursing services in health departments? What are our urgent problems that need our best thinking today? With one-third of the counties of this country without any public health nursing service in rural areas, with most of our country without really adequate provision for nursing care for those sick at home, with need for almost twice as many qualified public health nurses as are now available if we are to have even the minimum of 1 to 5,000 population, what can we do to give each nurse her right to be of maximum usefulness, to utilize to the limit her knowledge of public health nursing? What is good public health nursing in 1946?

The first principle of public health nursing administration that we teach our public health nursing students is that the total community health program should be viewed as a whole; and that services and agencies should recognize their contribution to that whole, and not, as is so frequently done, carry on their work as though they were independent of it. Moreover, a community health program is a *planned* program, planned by all participating groups under the leadership of the health officer. So far as public health nursing is concerned, the obligation of the health officer does not rest with planning the program of the nurses em-

ployed in his agency—it is to see that *all* public health nurses in his area are brought into the planning, and their work coördinated in the total program. The corollary, then, of this first principle of having the total community health program a planned program, is that the personnel of the department of health must be willing and able to give real leadership.

Planning should have as its objective the development of the best possible service to the community, the elimination of duplication and overlapping so as to meet as many of the health needs as possible, and to stretch the available staff over the most essential services before asking the community for increased funds for increased services. Public health nursing time is the most expensive single item in the budget of the health department, and it therefore becomes a part of wise planning to see that each visit made by a public health nurse is wisely spent and is a planned visit.

If we are to line up our community health needs in the order of their relative importance and attempt to eliminate wasteful visits, where does that land us? The most obvious and outstanding waste is probably found in those communities where public health nurses are employed by both private and public agencies. In cities of average size, at least, we know that multiplicity of agencies means a more expensive administrative overhead cost, more time spent on travel and less in actual public health nursing and, unless very careful planning is done in advance, there results a much less sharply defined program with many essential needs unmet. In 1946, therefore, the challenge to the health officer and the nurse in the health department is first that of bringing about an active community study of the total public health nursing needs, a frank evaluation by all concerned of unmet needs, and a friendly discussion

of what could result from pooled service under unified leadership and administration. Every public health nurse and health administrator should watch with great interest the experiments being conducted in such cities as Minneapolis and Seattle* where the visiting nurse association and the department of health nursing services have been pooled for an experimental period. The administrators of the Seattle service say in part, "The merger of the private visiting nurse association with the official Health Department in Seattle under a generalized nursing program including bedside care has proved to be a real success. . . . The continued separate existence of the two nursing agencies was both costly and inefficient, so it naturally followed that the two should merge." They describe in detail the ordinance passed by the City Council in order to effect the merger, the terms of agreement signed by the Visiting Nurse Association, the method used to bring all nurses under Civil Service, the retention in the merger of all the interests and assets of both groups. In appraising the results they state, "We made the same number of field visits after the merger as before despite the fact that we always had about one-fourth fewer nurses. . . . The generalized program was found to be more flexible and more productive of results; it eliminated useless duplication and distance of travel. . . . There was no loss in the quantity of work done for the specialized services as so many fear in a generalized program. . . . The educational services of the nursing division to all age groups increased 100 per cent." The Seattle study also describes the method taken to allow for the collection of fees by all of the nurses, and emphasizes the improvement made throughout the entire service as a result

* Dr. Westman, Health Officer for Seattle, and Miss Prindiville, the nurse director, have written a very helpful article in the *Public Health Nursing* magazine for June, 1945.

of encouraging each nurse to give the complete service in her families.

In this connection I would like to comment on the study of voluntary health agencies recently completed, which in effect recommends that all of those functioning in one community pool their strength to form one voluntary agency under one administration. In my personal opinion, I do not see visiting nurse associations joining in this fashion with other voluntary health agencies, since in the main the latter are not direct service organizations. Instead I believe we will do better to pool our program and service with that of the health department, for as two direct service agencies our interests are much more similar. This is a strategic time, therefore, to be conducting such studies on coördination, and we look to our departments of health to begin them. States like New York for several years have been advocating the development of correlated services, and it has been accepted throughout that state as the policy of the Bureau of Nursing of the State Health Department. In this connection also we can fortify our courage, if necessary, by turning to the statement made by the State and Territorial Health Officers a few years ago and to that on health department functions issued by the American Public Health Association. In essence both believe that it is proper and important that departments of health see to it that home nursing care of the sick be correlated with teaching services.

So much then for our planning to bring all of the public health nurses of a community into a generalized program. Let us now move on to consideration of another principle of public health nursing—that is, that no service, even though generalized, can be stronger than the *intake* policies under which it operates. Too many public health nursing programs do not control their intake policies, but rather are shaped

by them. As a result, the families who know how to use and call the nurses get the service, with little regard as to whether these same families are the types that most need it and can best profit from it. This is very true in the typical visiting nurse association and to a lesser degree in departments of health.

In 1946, therefore, public health leadership involves leadership through group discussions of relative values of types of public health nursing visits. In what groups in our community are our greatest sickness and death rates—by ages, by geographic distribution, by occupations, by income, and by racial groups? To what extent are our nursing intake policies designed to bring these groups and problems to the attention of the public health nurse? Where are our present visits going and how far do they aim at these public health needs? In many communities there is wide discrepancy between basic needs and actual service given. Attempts to correct this difference turn one's attention at once to the rôle of the hospital in the community health program and of its usual omission from it; and point to the necessity for developing nursing service in the community as an entity that unites home and hospital, curative and preventive nursing services, into one total program for the good of the patient. To accomplish this, a system of written referrals back and forth is necessary, which serves to refer types of patients and families automatically, and is not limited to the very occasional referral for an acute social situation when the nurse or doctor happens to remember.

By way of illustration, take the problem of the premature infant and the contribution which the public health nurse can make to its care. Here we have a group with high morbidity and mortality rates, a group to which a very expensive type of care is given while in

the hospital. A Negro pediatrician first called my attention to the waste involved in this care when he stated that in the hospital where his clinic for sick children was located it took less than a month from the time the premature was discharged home until it landed, a sick infant, back in his clinic. And he sagely added that good public health nursing service automatically directed to those homes could largely have prevented this.

We public health planners must be concerned with the *total* care given to prematures, making sure first that the hospital service given is safe and adequate. Next our plan should provide that a public health nurse routinely make a visit to the home of every premature infant *before* it is discharged from the hospital, and should insure that it will be discharged only when the public health nurse states that the home is fit and ready to receive it. It is extravagant to give weeks of expensive hospital care to a baby, only to discharge it to a home where the older children have a communicable disease or where facilities are inadequate for warmth, or where the mother lacks understanding of how to feed it. Therefore written coöperative agreements secured through joint planning of all groups concerned (medical, hospital, and public health) under the leadership of the health officer and his nurse, must develop a method whereby every such infant is reported at least two days before discharge and final plans are held pending report of that visit. The agreement further should provide that the public health nurse will also visit the day following discharge, and at regular intervals thereafter until the family doctor is sure that the baby and its family are able to make a go of it. Such visits take priority at the top of the list of visits that should be made promptly.

Or let us take children with rheu-

matic fever, who surely need good health supervision from public health nurses following their discharge from the hospital for convalescence at home. What happens on their return home? Is the family correctly interpreting the instructions regarding rest and play? Is the home such that a convalescent routine is possible? A community program for care of such children must include the participation of the public health nurse on an overall planned basis, because of the nature of rheumatic fever itself, not just because of the striking inadequacy of an occasional family.

Since public health nurses cannot give prenatal instruction to all expectant mothers in their area, does everyone concerned understand clearly which types they will follow, for how many visits, and why? Has such a need been discussed under department of health leadership by all the groups involved, a conclusion jointly arrived at, and a written agreement drawn up which insures automatic referral?

An admirable plan for the better distribution of hospital facilities for the United States has been embodied in Senate Bill 191, carrying the approval and support of medical, hospital, and public health authorities. You are familiar with its provisions for the smaller cities and rural areas whereby the hospital and public health programs are coöordinated and the health officer given a rôle of community leadership in the total program. While we certainly need a much better distribution of hospitals and many new institutions to give adequate service, it may be some time before we actually achieve them. In the meanwhile, we need not sit back waiting for the hundreds of millions to be made available, for there is an immediate coöordinating job to be done whether or not we ever get improved physical facilities—perhaps more needed when our facilities

are poor. The U. S. Public Health Service is proceeding to develop architects' sketches and floor plans for these new projected facilities. Concurrent with this, we in the communities should be developing *our* overall plans for unified *service*. Both blue prints are necessary, but one should not wait for the other.

The original need in health departments for the services of public health nurses to assist in the control of the acute communicable diseases has changed with the years, largely from that of supervising the isolation of sick children to that of reemphasizing preventive measures, family by family, with each new generation of children. The work of the public health nurse in 1946 is becoming increasingly that of persuading families to get medical services *before* they are ill, and of early case finding.

Dr. Shafer in a paper on control of the venereal diseases, has emphasized the shift in relative importance of medical treatment to case finding and follow-up. Here the public health nurse comes increasingly into the program. Moreover, as one studies in 1946 the specific needs of various population groups as shown by a breakdown of local health statistics, the problems of the aging population become distressingly evident. Early case finding in this age group is an obvious need, and the public health nurse's function in the reduction of deaths from cancer, heart disease, diabetes and other organic diseases of the older age group is at once apparent. But we will get little public interest or support for our program if we stop at case finding with this group. With the age of our population increasing, we are having an acceleration of the problem of securing adequate care for the chronically ill, since we have had no corresponding increase in available facilities. Here is a group for whom community planning

cannot be postponed, and no better leadership could be found to initiate such planning than that emanating from the health department itself.

The recent study in New York State of the care of the mentally ill, calls attention to the fact that a large per cent of the beds in state mental hospitals are occupied by types of patients for whom custodial care only is needed. Here is a program set up to care for the acutely ill, being retarded and complicated by this large group of senile patients because no other provision is made for them, while long waiting lists of acutely ill are unable to gain admission.

Connecticut has just completed a state survey of chronic illness among the indigent, and has made a series of recommendations for improvement of facilities for such care. As a nurse I was especially interested in the fact that, included in the plan with recommendations for special types of institutions, were recommendations for an increased number of nursing homes *under adequate medical direction*, and much more home care from public health nurses. The report states that home nursing care can to a considerable extent supplant institutional care if the public health nursing personnel is sufficiently increased. In this connection we should realize that in our communities, as more acute illness is hospitalized, the case load of the average visiting nurse association is weighted more and more heavily with chronic patients; and the well qualified visiting nurse is getting increasingly restless, feeling that in such a program she does not utilize her public health knowledge to the full. She agrees at once that such patients must have home care, that the public health nurse has a responsibility and much to offer in such homes, but she herself asks for some professional variety.

I have not time to go into the use of

the practical nurse in this program and the contribution that she can make if properly supervised. Even with her utilization the function of the public health nurse is evident. From the point of view of the shift in community needs, therefore, the completely generalized nursing program with one nurse to a district intrigues her, offering her as it does the chance to care for all of the public health nursing needs of the family from infancy to old age. And at this point it is unnecessary to remind practical public health administrators that the program which gains the most community appreciation and support is that one which gives the direct service for which the family has an urgent need at the moment. For in such moments a teaching program seems theoretical at best and frequently irrelevant in the light of the urgency for direct care. The success of visiting nurse associations from coast to coast in gaining financial support and the affection of the public is witness to this fact.

We have been discussing the expanding rôle of the public health nurse in the health department when working in a community health program which operates under the recognized leadership of the health officer. Such a program requires that she herself be capable of leadership, in her area acting as the representative of the health department and the public health nursing profession to bring about the most effective use of all resources to meet the health needs of her people. She must have a good scientific knowledge both of curative and of preventive nursing; she must have a practical working knowledge of vital statistics and the epidemiological approach to health problems; she must understand people—normal healthy people of all ages—the deviations caused by illnesses of various types, the problems created by acute mental illness; she must see her

rôle as a part of the group who work to find community solutions to community problems, and who exert the type of leadership in the community which the public recognizes as truly professional. No health officer working alone can deliver professional community leadership—he succeeds in direct relation to the group leadership he creates among his public health personnel. He knows this, and he appreciates that he can move forward only as the members of his group also understand the public health science on which this planning is based. Time is too short for him to be able to go back and teach these fundamentals to his personnel. There is too much wanting to be done. And the fun and challenge of his work is to be found in direct relation to the ability of his coworkers to pick up the ball and carry it along. Professional leadership means professional teamwork.

Therefore, it seems to me we should all be agreed that in 1946 the public health nurse in the health department must be a nurse exceptionally well prepared in public health nursing and public health science. There is no place here for the amateur, for the pace is too swift. At present few schools of nursing pretend to include adequate preparation for public health nursing in the basic curriculum. Minimum preparation, as outlined by the National Organization for Public Health Nursing and the American Public Health Association, consists of a year's university study in public health nursing following the school of nursing work. If the nurse does not now have it, the health officer should see that she gets it as soon as possible. Leaves of absence will be possible as more nurses are available. We look to the bureaus of public health nursing in state departments of health and to the universities to find scholarship and loan funds for those unable to study otherwise. An agency's current

staff education program is good in itself and important, but it cannot replace this essential preparation.

Perhaps the health officer has the right to challenge the public health nursing profession, and especially the universities at this point, and to ask that we place greater importance not only upon the education of the nurse for public health, but upon her selection. If she is to be both nurse and teacher, family health counsellor and friend, she must herself be a mature, emotionally stable person, able to be a loyal, dependable part of the public health team. I admit that many times we have not exercised sufficient selectivity or placed sufficient importance upon these personal qualifications. In the war years some fine nurses, unprepared in public health nursing, have been employed in health departments to fill vacancies made by the demands of military service. These nurses have proved that they have the *personal* qualifications needed for public health work, and it should be our concern that those who wish to remain in the field should now add the professional qualifications which are equally essential for a real career in public health nursing.

I have said that few schools of nursing give adequate preparation in public health nursing, but that does not mean that it cannot be done. We have in this country a number of university schools of nursing, such as those at Skidmore, Vanderbilt, and Yale, whose graduates are prepared to enter the field of public health nursing at staff level without stopping for the additional year of study now necessary for graduates of other schools. Nurse educators badly need the help of all interested members of public health associations to lend support to their efforts to strengthen the basic education of all of

the students in our schools of nursing. All students graduating from schools of nursing should have had experience beyond that of the usual medical, surgical, pediatric, and obstetrical services. As we develop community health programs with the nursing services in hospital and community linked together, as nurses in hospitals utilize their opportunities to teach health and sickness prevention while they give care to the sick, we can see that every nurse must have a good working knowledge of communicable disease and tuberculosis nursing, of the care of well children and of mental nursing. Facilities for these experiences are available in every state if wisely utilized. Public opinion must support our efforts to require such experience for all students, for no community service can be any better than the professional preparation of the group that renders it.

At our annual meetings and in our publications we have had valuable and stimulating discussions of public health measures for control of various types of communicable disease. I am calling attention to the fact that we must have equal concern for the better *distribution* of nursing service, for without it we have no assurance that the nurse will get to the right place at the right time.

In summary then, I would assert that probably no profession today faces greater challenges than does that of public health—and no group has greater opportunities than has the public health nursing group. We, under aggressive, constructive leadership from our health departments, can redistribute the nursing services now available to our communities so that they will give values far beyond those now being given, and through application of our scientific knowledge make our public health dollar pay still greater dividends.

State Variation in the Collection of Reportable Disease Statistics

ANTONIO CIOCCO, Sc.D., MARGARET D. WEST, AND
MARION E. ALTENDERFER

Division of Public Health Methods, U. S. Public Health Service, Washington, D. C.

THIS paper is presented as the first in a series of studies of the current status of morbidity reporting. In a recent paper,¹ Perrott outlined the important problems of morbidity reporting from the standpoint of national public health activities as:

1. Measurement of the level of under-reporting
2. New methods for getting better coöperation from physicians and institutions which furnish data
3. Selection of diseases to be reported from all states
4. Reporting and recording certain characteristics about the diseases and individuals in order that the data will have greater value as a measure of the state of health of the nation

To analyze these problems, a series of pilot studies in coöperation with state and local health authorities is being conducted. Since the accuracy and completeness of the statistics published by the Public Health Service are related to the methods of collecting and filing morbidity data by the state health departments, this first paper summarizes an inquiry into such procedures.

The need for nation-wide statistics on the incidence and prevalence of epidemic diseases was recognized by law nearly 70 years ago. The National Quarantine Act of 1878 and the 1893 revision authorized the Secretary of the Treasury, who had jurisdiction over the Marine Hospital Service, to obtain reports of cases of infectious or contagious diseases both from state and municipal

health authorities in the United States and from consular offices abroad. An Act of Congress in 1902 made it the duty of the Surgeon General of the U. S. Public Health Service to prepare and distribute forms for the collection and compilation of morbidity statistics and have these statistics compiled and published as part of the health reports of the Service. The Public Health Service Act of 1943 contains a similar provision.

Since 1878, procedures for the collection and publication of national statistics on the reportable diseases have developed through the coöperative efforts of the Public Health Service and the several state health departments. These efforts have been stimulated primarily by the Annual Conferences of State and Territorial Health Officers which have been held since 1903.

As a result of the discussions at these Conferences of the problem of improving morbidity reporting, several important steps have been taken. In 1913, a model state law for morbidity reports and a model notification blank were adopted by the Conference. The model law proposed a list of 41 diseases, in addition to occupational diseases and injuries, to be reported. Since that time a number of states have passed laws based on the model. Over half the states have adopted a reporting card similar to the model notification blank.

In 1914, the Public Health Service appointed collaborating epidemiologists to serve with certain state health de-

partments. Later this plan was extended and assistant collaborating epidemiologists were appointed in local jurisdictions. These persons are agents of the federal government, therefore they are entitled to use penalty envelopes and cards in the collection of morbidity data. This use of penalty mail was a considerable stimulus to reporting, since it saved physicians the trouble and expense of postage. Some ten years later the creation of a morbidity registration area was suggested,²⁻⁷ but such an area has never been set up.

REPORTING PROCEDURES

An analysis by Fowler⁸ of laws regarding reportable diseases indicates that there is great variation from state to state both in the number of diseases reportable and in the diseases included. The number of diseases reportable (exclusive of occupational diseases) varies from 28 in Virginia to 66 in Iowa. Occupational diseases are reportable in 24 states. Only 12 of the communicable diseases—conjunctivitis, diphtheria, measles, meningitis, poliomyelitis, scarlet fever, smallpox, syphilis, typhoid fever, tuberculosis, undulant fever, and whooping cough—are reportable in all 48 states and the District of Columbia. The average number reportable (exclusive of occupational diseases) has increased from 40 in 1933 to 48 in 1944.

State health departments differ in the organization of their reporting systems and in the procedures followed in the collection of morbidity data. Many of these differences are due to peculiar conditions and needs which prevail in the individual states, and are related to the evolution of the health departments in the states.

In order to study the reporting procedures among the states, information on the formal aspects of their procedures was obtained from the state health officers by means of a questionnaire.

Each state health officer was asked the title of the division or divisions responsible for collecting and compiling morbidity data, the steps taken to evaluate the completeness of reporting, and, for each of 23 diseases, the types of files maintained. In addition he was asked to submit samples of the report, file, epidemiologic and other cards and records used in collecting and maintaining morbidity records.

Uniform requirements — There are only two reporting requirements which are uniform in all states: First, every state requires that cases of notifiable diseases be reported by the attending physician or, in the absence of a physician, by a householder, head of family or person in charge of the patient. Second, the reports are to be made to the local health authority. In actual practice, these requirements are frequently not carried out. In effect, therefore, even these procedures vary from state to state.

Reports received by local health authorities—There are several basic types of cards used for the physician's report to the local health authority. Seventeen states use the same card for all diseases, 13 have a special card for tuberculosis cases, and 29 for cases of venereal disease. Twenty-seven states and the District of Columbia use an individual penalty card similar to the model notification form. Nine states use a multiple case penalty card. Two states use a stamped card, 3 a card requiring postage, 3 a form other than a postcard, and 4 do not have a regular communicable disease report form.

There is variation from state to state in the items of information on the cards. The name and age of the patient and the name of the disease are the only items included on all cards. The sex of the patient is included on all but 2 of the 45 cards and his address on all but 3. Race or color is asked for on 82 per cent of the cards and the date of

onset on 71 per cent. Approximately three-fourths of the cards call for the name and address of the person reporting the case and the date of the report. A list of the diseases reportable in the state is printed on 76 per cent of the cards. Marital status, occupation, and place of occupation or school are each on less than half of the cards. Data about the household are included on only a few cards. Twenty-six cards have a note to use a special card for reports of venereal disease and 7 for reports of cases of tuberculosis (Table 1).

TABLE 1
Analysis of Communicable Disease Report Cards

<i>Items Included on Card</i>	<i>Number of States</i>	<i>Per cent</i>
Total states with cards	45	100
List of notifiable diseases	34	76
Description of patient		
Name and age	45	100
Address	42	93
Sex	43	96
Race or color	37	82
Marital status	9	20
Occupation	14	31
Place of business or school	21	47
Description of household		
Name of head	11	24
Occupation of head	2	4
Number in household	9	20
Number of food or milk handlers	12	27
Description of disease		
Name	45	100
Date of onset	32	71
Date diagnosed	9	20
Source of infection or place contracted	12	27
Person reporting		
Name and date	37	82
Address	32	71
Note to use special card for:		
Venereal diseases	26	58
Tuberculosis	7	16

Reports received by state health departments—In most states the original report cards received from physicians are forwarded to the state health department after a record has been made in the local office. In some states, however, these cards are retained by the local health officer and copies or summaries sent to the state health department. A few states require that physicians report cases of certain diseases

both to the local and to the state health officers. An immediate telegraphic report to the state health department, either by the attending physician or by the local health officer, is required by many states for cases of such diseases as meningitis, poliomyelitis, diphtheria, and smallpox. Daily, weekly, or monthly summaries of the number of cases are sent to the state health department by the local health officer in many states.

Division of state health department receiving reports—In 11 states all morbidity reports are received, tabulated, and filed in one statistical or preventable disease division. In 3 additional states all the reports are received by a division of preventable disease but are tabulated and filed by a central tabulating or statistical section. Twenty-nine states and the District of Columbia have a separate bureau which handles venereal disease reports. In 16 states tuberculosis reports are received by a special division. Eleven divisions of industrial hygiene and 4 divisions of cancer control receive direct reports.

Checking of reports—The reports received by the state health department are checked against death certificates in 35 states and the District of Columbia. In 20 states, reported cases are checked against both death certificates and laboratory reports. In 1 state they are checked against laboratory reports alone. Two states check death certificates for tuberculosis only. A few states also check reported cases against selective service examinations, hospital or clinic records, newspaper reports, or other data. Ten states make no outside checks.

Filing procedures—To obtain information as to the types of files used by the state health departments, the following questions were asked about 23 diseases:

1. Is the disease reportable?

- 2. If reportable, are cases reported to the state by name of patient?
- 3. If reportable by name, is there a separate file for the disease?
- 4. If reportable by name, are reports filed alphabetically by name of patient?
- 5. If reportable by name, are individual case records put on punch cards?

Very few states keep uniform files for all diseases. The extent of the variation in the type of files can be demonstrated by an analysis of the systems used for the recording of four diseases which are reportable in all states—diphtheria, malaria, measles, and poliomyelitis (Table 2).

TABLE 2
Number of States Using Specified Type of Files

Type of Files	Polio- myelitis	Diphtheria	Malaria	Measles
Total, disease reportable	49	49	49	49
Total, disease reportable by name of patient	45	39	37	32
Disease separate, alphabetically by name of patient	27	18	20	10
Disease separate, not alphabetically by name of patient	13	12	9	8
Not filed separately	5	9	8	14
Punch card system	17	15	14	12

Alphabetical files for an individual disease are maintained most frequently for serious diseases such as poliomyelitis, and least frequently for childhood diseases such as measles. The majority of the states maintain separate files for cases of poliomyelitis. More than half of them maintain separate files for diphtheria and malaria, but only a third separate the cases of measles.

Punch card systems are used to a greater or lesser degree in 29 states. Eleven of these use the system only for venereal disease records, 6 for special groups of disease, and 12 states use punch cards for all reportable diseases.

DISCUSSION

At present, it is possible to secure nation-wide statistics for only 12 dis-

eases. For each of the other 50 or more reportable diseases no national totals can be arrived at because none of these diseases is reportable in all states. Since the reasons for the inclusion or exclusion of many diseases in the reportable list may be based on historical rather than current epidemiological considerations, critical study of the present state and national reporting requirements would seem to be desirable. A first approach to this problem has been made by Stevick.⁹ On the basis of his studies the North Carolina State Board of Health adopted a list of 35 diseases to be reported in that state.

Within the limits of the diseases required to be reported, considerable variation exists among the states in the procedures used in the reporting and recording of morbidity statistics. Many of these variations are such as to affect the completeness and comparability of the statistics, and even the immediate usefulness of the reports received.

1. Much has been made of the value of penalty cards in stimulating reporting. If the effect of their use is significant, then it would be expected that a difference in completeness must exist between states which do and do not use penalty cards. Similarly, differences in completeness may be caused by the use of individual cards in some states and multiple case cards in others. Further study is needed to evaluate the relative advantages and disadvantages of both types of cards.

2. Within the framework of the present reporting requirements there is great variation as to the inclusion of such details as address, sex, and race of patient, date of onset, and name of person reporting the case. In some states part of this information is secured when the epidemiologic follow-up is made. Presumably information should be obtained on the report card to the extent, and only to the extent, that it is of value

in the investigation and control of disease.

Studies on the incidence of disease are of sharply limited value when data on age, sex, race, and date of onset, are not available. At the present time, neither at the national level, nor even in some states at the state level, can the incidence of disease be studied in terms of these very important factors. There seems to be a real question, in the face of the variety which exists, as to the optimum amount of information which should be included in the original reports.

3. The accuracy and completeness of reports may also be affected by the organizational set-up of the state health departments. In some states one division receives all reports, in others separate divisions handle the reports of certain diseases. In the latter case there may be an increase in accuracy if extra checks are made; on the other hand, such gains may be offset by lack of coördination between the units of the health department.

4. Underreporting of cases is known to exist to a greater or lesser degree for all diseases and in all places. Health departments routinely receive death reports, laboratory reports, and other collateral material about illnesses. If these data are checked against morbidity reports, two useful purposes are served—a crude index of the completeness of reporting can be obtained, and at the same time, unreported cases are picked up, increasing the completeness of reporting.

Since these checks are not made uniformly by all states, the net result is probably to intensify existing differences in completeness and comparability of reporting. This is at least suggested by an analysis of the average number of cases of meningitis, poliomyelitis, scarlet fever, and pneumonia reported per death in the 5 year period 1938-1942. The 36 states (including the District

of Columbia) which make a routine check of death certificates reported an average of 38 per cent more cases of meningitis per death, 20 per cent more cases of poliomyelitis, 51 per cent more cases of scarlet fever, and 38 per cent more cases of pneumonia than do the 13 states which make no such check (Table 3).

TABLE 3

Relation between Checking Procedures and Ratio of Cases to Deaths

Disease	Average Cases per Death 1938-1942 for States Which:	
	Check Death Certificates	Do Not Check Death Certificates
Meningitis	3.3	2.4
Poliomyelitis	10.0	8.3
Scarlet fever	231.5	153.1
Pneumonia	2.2	1.6

5. A useable filing system can be one of the most helpful tools of the morbidity reporting system. Separate files by disease and by name of patient make it possible to find and eliminate duplicate reports; and, for chronic diseases, to separate new from recurrent or relapsed cases, or cases coming under the care of an additional agency. Such files also make it easier to use collateral data for checking the completeness of reporting. Here, existing differences in procedures have a real effect on whether reports are of incidence or prevalence, as well as affecting the completeness and accuracy of the reports.

CONCLUSION

The value of national morbidity statistics hinges on the completeness, accuracy, and comparability of the data emanating from states. A review of the present status of morbidity reporting indicates that the lists of diseases reportable, the amount of information required about each case, and the manner in which the reports are transmitted and recorded have considerable variation from state to state. It follows that the

validity of comparisons among the states may be questioned and an accurate statement of the nation-wide incidence of any reportable disease cannot be obtained.

It is now 32 years since the first comprehensive discussions and recommendations as to the notification of the occurrence and prevalence of certain diseases were made by the Conference of State and Territorial Health Officers. Since that time, reporting procedures in the various states have developed in different ways according to the organization of the health departments in the states. If the resulting experiences of the states were brought to bear on reporting problems, it should be possible to measure the value of alternate procedures and to arrive at those which make for the most complete and accu-

rate reporting of the diseases that are of public health importance today.

Massachusetts Develops Blood Program

Geoffrey Edsall, M.D., Director of the Division of Biologic Laboratories of the Massachusetts State Department of Public Health, Boston, has announced that the blood program recently authorized in Massachusetts began operation in December, 1945, when the mobile unit visited five cities and towns in the southeastern part of the state, collecting several hundred pints of voluntary blood donations. Dr. Edsall reports that the department's emphasis is now placed on fractionation of blood to fit the program to the newly released supply from the American Red Cross of Army-Navy plasma. The new laboratory of the department, in Jamaica Plain, is expected to be occupied during April, and in the meantime fractionation is being carried out

on a limited scale with the collaboration of the Department of Physical Chemistry of the Harvard Medical School, Boston.

Plans have been submitted to the Legislature for expansion of the program to include two mobile units so that the state may be covered more effectively and an adequate supply of blood for the needs of the state may be obtained.

Dr. Edsall reports that it is the intent of the department, as soon as blood collections begin to come in on a regular schedule, to undertake the distribution of whole blood on a small scale at first, gradually expanding the service as experience is accumulated in solving the problems which it presents.

Disinfection of Air by Germicidal Vapors and Mists*

Laboratory Section

DURING the past year several studies on the effect of dispersing glycol vapors into atmospheres inhabited by human beings have been published. Certain of these investigations have been concerned only with the bactericidal activity of the vapor, while the others were directed primarily toward determining whether or not the incidence of acute respiratory disease could be diminished by maintaining a constant germicidal concentration of the glycol in the atmosphere.

One study on the effect of triethylene glycol vapor on a single respiratory pathogen, namely, the hemolytic streptococcus^{1,2} reported in last year's summary, was extended to include a period of relatively low humidities, i.e., 20 per cent to 30 per cent relative humidity.³ While the reduction of air-borne streptococci was not quite so pronounced as when the relative humidity was maintained at 40 to 50 per cent (a reduction of 95 per cent occurred under these conditions), the effect was still substantial, being only 15 per cent less at the low humidities.

Another study on the intermittent dispersal of propylene glycol into the atmosphere of a crowded room⁴ showed a diminution of 80 per cent in the total bacterial content of the air which lasted for about 15 minutes only. Repeated dispersions of the glycol vapor every 15 minutes resulted in a fairly constant lowering of the bacterial population of the air.

The report of the 3 years' study of the clinical application of the disinfection

of air by glycol vapors in a children's convalescent home showed a marked reduction in the number of acute respiratory infections occurring in the wards treated with both propylene and triethylene glycols. Whereas in the control wards 132 infections occurred during the course of the three winters, there were only 13 such instances in the glycol wards during the same period. The fact that the children were, for the most part, chronically confined to bed presented an unusually favorable condition for the prophylactic action of the glycol vapor.⁵

An investigation of the effect of triethylene glycol vapor on the respiratory disease incidence in military barracks⁶ brought out the fact that, while for the first 3 weeks after new personnel entered the glycolized area the disease rate remained the same as in the control barracks, the second 3 week period showed a 65 per cent reduction in acute respiratory infections in the glycol treated barracks. Similar effects were observed in respect to air-borne hemolytic streptococci and throat carriers of this microorganism.

Several Canadian workers⁷ made a brief study of introducing propylene glycol into army barracks. They found that bactericidal concentrations could not be employed without condensation of the glycol on the walls, windows, etc. (triethylene glycol is greatly superior in this respect). While the study was not continued long enough to secure any significant data on the incidence of respiratory infection in the test and

* Referee's report to the STANDARD METHODS COMMITTEE FOR THE EXAMINATION OF GERMICIDES AND ANTIBACTERIAL AGENTS. Committee authorized 1941. Published Reports, *A.J.P.H.*, May, 1943, Aug., 1944, and Aug., 1945.

control barracks, they did find a reduction of air-borne bacteria in the glycol containing atmosphere amounting to 65 per cent as compared with air of the control spaces.

The use of sodium hypochlorite has been further studied as an aerial disinfectant⁸ by means of introducing this agent in the form of hypochlorous acid gas. While this vapor has a marked bactericidal action, it requires a high relative humidity, 70 to 90 per cent, for its optimum effect and also exerts a corrosive action on many metals. Its usefulness would seem to be limited to crowded spaces where there is little ventilation and presumably a high relative humidity.

Substances other than those cited above are being studied for their aerial disinfecting properties. A report on the use of lactic acid as a germicidal vapor⁹ indicates that this compound exerts a marked lethal effect on air-borne bacteria when employed in concentrations of 1 gram of lactic acid dispersed in 200,000,000 ml. of air or less, approximately the same order of effectiveness as triethylene glycol. The difficulty about employing this agent in atmospheres occupied by human beings is that it has a slight odor.

Progress continues in the development and testing of apparatus for the dispersion of glycol vapors and the control of their concentration in the air. While the principles of such apparatus have been rather satisfactorily worked out, the actual production of dependable instruments has not yet been achieved. Since this is an entirely new field, a great deal of detail has to be learned by trial and error. In respect to vaporizers, there is little to add to the summary of a year ago. Concerning the device for the automatic regulation of glycol vapor in the air, the glyco-stat, more can be said. This instrument has now been calibrated so that variations in the intensity of the

light reflected from the glycol-condensing surface of the wheel can be read directly as corresponding degrees of saturation of the air with the glycol vapor present.¹⁰ Thus the glyco-stat can be set for any desired per cent saturation of glycol in the air, and the vaporizer will maintain this concentration. By means of connecting the glyco-stat with a milliamperere recorder we can obtain a continuous record of the per cent saturation of glycol present in the air, which is of course of great value in conducting experimental studies. It has been found that relative saturation of the air with a glycol vapor is of much more significance in respect to germicidal activity than is the actual content in milligrams of glycol per liter of air.

A PRAYER FOR IMAGINATION

THE psychology of the United States of America does not present a very heartening picture today. Bulging with food and oozing prosperity, we complain about butter and nylon stockings. Our labor unions strike for higher wages—often with justification relative to rising prices. Our business leaders fight with equal vigor—and less justification—for increased profits. Powerful lobbies attempt to block the vital national housing program and the equally important program of social security.

Our contentious congressmen are—too many of them—concerned only with personal prestige and the defense of special vested interests. They appeal to the basest motives by invoking a violent and selfish nationalism to delay every step proposed for devoting our surplus to the salvation of a starving world. We can only hope for the realization of that most moving of all prayers, "Father, forgive them, for they know not what they do."

We are like Helen Keller at the beginning of her career, with no eyes to see, no ears to hear, cut off from the world in a terrible and blinding isolation of the spirit. May we gain the imagination, as she did, to learn that there are realities beyond the objects which we can touch with our hands.

Statistics from Greece, recently released by UNRRA,¹ may help the public health worker to gain a glimpse of what famine really means—famine such as will again prevail this year if the United States does not awake from its lethargy.

In thirty departmental capitals of Greece, the birth rate in 1940 was 22 per 1,000 and the death rate was 13. In 1942, the birth rate was 12 and the death rate, 37.

For Athens and the Piraeus, where more detailed statistics are available, the general death rate similarly tripled between 1940 and 1942. Though there were no serious outbreaks of acute epidemic disease, the infant mortality rose from 90 to 231 per 1,000 births; and the tuberculosis death rate for 1942 reached 456 per 100,000. Of a total of 41,000 deaths, 17,000 were cases of simple starvation. Analysis of deaths by age-periods showed that the mortality at 50 years of age

was equal to what it was in 1940, at 70 years of age. In 1943, with the influx of relief supplies the death rates returned to normal.

More recent statistics² for certain European municipalities show that the infant mortality rates in three large Dutch cities increased by from 132 to 176 per cent in 1945, as compared with 1944; and, in seven French cities, the corresponding increases varied from 24 and 52 per cent in Lille and Paris to 141 per cent and 154 per cent in Nantes and Strasbourg.

These statistics mean something to us who speak the language. Perhaps we can help others to comprehend their significance, in the light of the famine which today threatens many quarters of the globe. We, in the United States have promised 6 million tons of wheat to UNRRA for 1946; and had recently delivered about 3 per cent of that amount, while Canada had already delivered one-third of her quota. The State Department has recently estimated that for every million tons we fall short on our allotment, 20 million people will starve to death. The Food and Nutrition Section of our Association is deeply concerned with this problem. It urges in the strongest terms the importance of general participation in President Truman's program of voluntary rationing. If this fails to meet the need, a return to compulsory rationing would be clearly indicated.

THE F. N. S. COMES OF AGE

IN May of this year, the Frontier Nursing Service, with headquarters at Wendover, Leslie County, Kentucky, celebrates its twenty-first birthday.

Mary Breckinridge, the impassioned and indomitable founder and head of this enterprise was of old Kentucky stock and she knew her mountains. She not only knew them, she determined to do something about them. In a region of nearly a thousand square miles, there were three little towns of 200-300 inhabitants. More than 28,000 of the total 29,000 population lived in lonely cabins and shacks scattered along the rivers and up the creeks and branches which cut through the deep canyons of the hills. There were only a few miles of paved road leading to the county seat. All other access was by rough horseback trails. The people (99 per cent "mountain whites") were desperately poor. There were no hospitals, practically no physicians available. It was the American backlands at their very worst.

Mrs. Breckinridge added an English qualification in midwifery to her nursing background. She studied what was being done abroad, particularly by the Highlands and Islands Medical and Nursing Service of Scotland under Sir Leslie Mackenzie. She formed her organization "to safeguard the lives and health of mothers and children by providing and preparing trained nurse-midwives for rural areas in Kentucky and elsewhere where there is inadequate medical service; to give nursing care to the sick of both sexes and all ages; to establish, own, maintain and operate hospitals, clinics, nursing centers, and midwifery training schools for graduate nurses; to educate the rural population in the laws of health, and parents in baby hygiene and child care; to provide expert social service; to obtain medical, dental, and surgical service for those who need them, at a price they can afford to pay; to ameliorate conditions inimical to health and growth and to conduct research toward that end." In May, 1925, she and two other devoted nurse-midwives moved in; and the news spread from Thousand Sticks Mountain

to Hell-for-Sartin Creek that there was something new in the framework of a society that had been untouched by the outside world for two centuries.

Today, the F. N. S. operates a hospital, with 18 beds and 8 bassinets, and three log houses at Hyden, six major nursing centers and five other small clinic centers in various parts of the area. It has in addition to Mrs. Breckinridge, a medical Director, a Dean of the School of Midwifery, and seventeen nurses, including supervisors and staff. It has a research director, a social service secretary and a statistician, besides clerical and accounting personnel and a large group of unpaid volunteers. In the first 20 years of its existence, the service registered 17,358 children and 10,039 adults. It delivered 5,963 babies. It administered 136,604 protective inoculations. It paid 363,432 visits to the home, and registered 434,662 visits to clinics. It gave 71,896 days of hospital care to 7,277 patients.¹

The F. N. S. has three outstanding achievements to its credit. In the first place, it has demonstrated the extraordinary efficiency of the nurse-midwife in dealing with the problems of childbirth. Out of 6,263 deliveries up to January, 1946, there have been but 6 maternal deaths—a record which can be judged in the light of the fact that in similar regions the maternal mortality rate is nearer 10 than 1 per 1,000.

Second, this program has shown that—given sufficient courage and initiative—it is possible to bring the benefits of modern public health science to the most economically handicapped areas of the American continent.

Third, this gallant enterprise has given to all who know it at first hand, an inspiring lesson in the potential greatness of the human spirit. From Mrs. Breckinridge—who has conceived and planned the job and by her tireless efforts and moving eloquence raised the funds for its support—through the expert staff and down to the youngest volunteer—all have borne trials and overcome difficulties that in prospect seemed insurmountable. Riding the icy trails, swimming the swollen rivers, they have fulfilled their appointed tasks. One nurse died of an appendix ruptured in a wild ride and ignored while she continued her day's work to the end. Another nurse, and the Director herself, suffered horseback accidents which narrowly escaped fatal results. Ernest Poole closes a moving book on the achievements of the Service² with this passage: "Garibaldi long ago said to the men of Italy: 'What I have to offer you is fatigue, danger, struggle, with risk of death; the chill of the cold night in the free air, and heat under the burning sun; no lodgings, uncertain provisions, forced marches, dangerous outposts. Those who love humanity and their country may follow me!' The Frontier Nurses are like that."

A NEW FORCE IN THE REFORM OF MENTAL HOSPITALS

THE readers of this *Journal* are in general aware that the status of our public mental hospitals is one of the least admirable aspects of our civilization. The Editor still vividly recalls his astonishment when a national authority in this field praised a certain institution of this type which was known to be overcrowded, undermanned, and operating on a per capita budget far below that of the jails and almshouses of the state. Yet the speaker was no doubt correct in comparing this particular hospital with those of the country as a whole.

The degree of personal understanding to which the mental patient is subjected is perhaps even more important than the quality of the food and the shelter with which he is supplied. As Dr. A. H. Eichert has said, "According to the usual set-up in a modern hospital, attendants are supposed to have the duty of carrying out the doctors' orders, with little of their own personalities entering into the situation. On the other hand, the contacts between the physicians and the patients are so short and few that it is the attendants rather than the physicians who interpret the hospital to the patients." Yet the attendants who occupy this crucial position are almost universally handicapped by low pay, absence of any special qualifications, and complete lack of training for their task.

Into this situation, aggravated by general wartime lack of personnel, there entered 2,000 conscientious objectors, young men of earnestness and, in many instances, of high intellectual and academic qualifications. In 57 institutions, they have fulfilled for four years the tasks of bed-pan carrying, feeding and washing of patients, changing of bed linen, with a faithfulness which alone made it possible to carry on with some degree of efficiency.

They provided, however, much more than performance of routine duties. They thought of what they were doing, they learned to understand it, they realized the fundamental inadequacies of the whole procedure. In 1944, they organized "The Mental Hygiene Program of Civilian Public Service" for the enlightenment of their own members, of the mental hospital attendant group as a whole, and of the general public, upon whose understanding the ultimate solution of this problem must depend. They have avoided all sensationalism, worked with and not against hospital administrators, proceeded slowly and scientifically toward the goal of better care of the insane.

They have a strong legal committee which is studying the legislation of all the states with respect to mental disease and preparing the draft of a model mental hygiene law. They have issued excellent pamphlets describing the work of the mental hospital attendant which can serve as elementary textbooks in the field. They are attempting to acquaint the public with the real objectives and problems of the mental institution by describing in popular form the work of certain selected hospitals.

Since 1944, they have published a monthly journal *The Attendant*—a name now changed to "The Psychiatric Aid."¹ The following titles of articles appearing in recent issues give some conception of its scope: Training Programs for Low-Grade Defectives; A Symposium on Institutional Architecture; A Subjective Account of Electroshock Treatment (by a patient); A Symposium on the Supervision of Patient Crews; and many expositions of the principles of mental hygiene which the attendant should follow in dealing with the patient.

This may well be the dawn of a new day in the management of mental hospitals. Benjamin Rush was a physician, Dorothea Dix, a reformer, Clifford Beers, a patient. Now, for the first time a group of intelligent young men have seen this problem from the inside, have lived and suffered with the patients, as no doctor and no outside reformer can hope to do. They have let light into one of the dark places of the earth. Clifford Beers would have rejoiced in this episode; and it is good that his National Committee for Mental Hygiene stands behind these young men in their important work.

BOOKS AND REPORTS

Books of Special Interest to Public Health Workers
Published in 1944 and 1945

*"For out of old felde, as men seith
Cometh all this newe corn fro yeer to yeer
And out of old bokes, in good feith
Cometh al this newe science that men lere."*—Geoffrey Chaucer

THE two years since the JOURNAL's latest book review edition have been full of ferment in many areas, in public health no less than in others. They have, for example, seen great forward steps in administrative planning, such as the Association's Medical Care Statement and the President's Health Message, the introduction of important federal legislation, such as Senate Bill 191 for the construction of hospitals and health centers, the comprehensive review of voluntary agencies, development of the National Health Reporting Area, and the planning for a nationwide system of local administrative units of economy and efficiency. They have also seen the end of a war in which deaths due to war wounds were amazingly low because of the efficacy of blood plasma, the sulfa drugs, and penicillin, none of which were available during the last World War. Because of this and because of the vast scope of the war itself, the physical and mental rehabilitation of war veterans will increasingly concern the professions.

With the end of the war in mid-1945, renewal of scientific and medical communication with the rest of the world began. Not too much of this communication has yet been reflected in books received, but there is no doubt that the war-torn areas have in the future much to report by way of relevant experience, if only they can be kept alive for the better days when the international exchange of scientific in-

formation is again a part of normal communication.

It is obvious that any selection of books for special mention by any individual or group will, in the words of the Book of Common Prayer, do "those things that ought not to have been done, and leave undone those things that ought to have been done," in the opinion of any other individual or group. This is as true of the present selection as of any other; it is our hope only that the list is both catholic and discriminating; that it does not include unworthy books. It has been selected on the basis of reviewers whose competence has been proved and reflects their opinions rather than those of the authors. Selections have been made from reviews appearing in the 1945 volumes of the *American Journal of Public Health*, *Journal of the American Medical Association*, *Canadian Medical Association Journal*, *British Medical Journal*, *Lancet*, *Journal of the Royal Sanitary Institute*, and *Canadian Journal of Public Health*. Hence, among the selections are books that were published in 1944, as well as in 1945. It should also be noted that the absence of a title is without prejudice. We should be more than human if all that were good had come to our notice and were recognized in their exact place on the scale of excellence.

BIOGRAPHY AND HISTORY
Essays in the History of Medicine

Presented to Professor Arturo Castiglioni on the Occasion of His Seventieth Birthday has 25 contributors who, spurred on by their affection for the one honored, wrote quite important essays which they might not otherwise have done. The variety of historical subjects is itself tribute to Dr. Castiglioni's own *Comprehensive History of Medicine*, written in Italian and translated in 4 other languages. Included in the "Festschrift" volume are essays from 7 countries written in 5 languages—the history of colonial hospitals in Spanish America; diabetic diets in the pre-insulin era; medical matters in Marco Polo's book of travels; and Ozanam, the epidemiologist, among others. "This is medical humanism at its best and our modern medical world gains richly from such an alliance of science and letters."

Another volume of "esoterica" is *The Falling Sickness: A History of Epilepsy* from the Greeks to the beginning of Modern Neurology, by Oswei Timken. It is "not merely for the epileptologist but for all physicians and indeed all educated people who wish to increase the depth and the perspective of their knowledge and their sympathies." The author has combed the literature of the ancient and medieval world, sought the opinion not only of noted physicians and university professors, but of village practitioners—even charlatans, of churchmen, and the common man. The result is both a panorama of seizures and a view of the painful progress of medicine—clear, readable, and at times amusing. It has no historical rival and occupies a separate shelf in the reviewer's Library of Fame.

A historical volume of peculiar interest is *Galen on Medical Experience*, the first edition of the Arabic version with English translation and notes by R. Walzer. This restores to the world one of the earliest of Galen's works, the

original text of which has been lost. It makes available one of the best of Galen's treatises and adds greatly to our knowledge of the ancient empirical school of medicine. This book will delight students of medical history, as well as those interested in philosophy and the late Greek writers, and is an easy passport to Galen's mind. *American Medical Practices in the Perspective of a Century*, by Bernhard J. Stern, on the other hand, proclaims its modernity with its sponsorship by a Committee on Medicine and the Changing Order of the New York Academy of Medicine. Inspired by necessary adjustments in the provision of medical care required by "a new medical science called upon to serve a new type of society," it is informative, accurate, and short. The series of which it is a part should exert a great influence in molding public opinion and in educating physicians.

With both antiquarian and current interest, Erwin H. Acherknecht's *Malaria in the Upper Mississippi Valley 1760-1900* is a supplement to the *Johns Hopkins Bulletin of the History of Medicine*. It should prove useful in work with or further study of malaria problems. For the general health worker or the casual reader it gives a vivid and authentic picture of the scourge of malaria during colonization of this area. Primarily factual, it is extremely interesting and informative for him who reads it carefully.

The year brought biographies of two notable pioneers. *A Biography of Julius Tandler*, by Alfred Goetzl and Ralph Arthur Reynolds, reviews the career of a pioneer in public health. As City Welfare Councillor of Vienna after the first World War, Tandler was responsible for the sound and brilliant developments of public health in the Austrian capital. He believed that every individual has a right to health and that the physician should occupy

a position in the social structure similar to that of the judge, teacher, or priest who are supported by society as a whole. Those were fighting words a generation ago. Rachel Baker's story of Elizabeth Blackwell, *The First Woman Doctor*, epitomizes the 100 year history of American women in medicine at the end of which "the contributions and even the indispensability of women in some fields of medical science are unquestioned." This is the simply told narrative of the woman who, as a little girl, decided she would "be something hard" when she grew up.

Two volumes of scientific history have also been high among the years' offerings. *The Autobiography of Science*, edited by Forest Ray Moulton and Justus J. Schifferes, "presents the highlights of scientific progress from the dawn of history to the present," through specific passages from the scientist's writings selected by the editors—"excerpts that are not mere fragments, but well written papers." For those interested in public health there are "two excerpts from anonymous Egyptian physicians, four from Hippocrates, and continuing with highlights in medicine, chemistry, and public health to the present time." Described as a "mental feast" to "be enjoyed by every intelligent layman." Also George Baitsell edited the 4th series of *Science in Progress*, a Scientific Book Club selection. This is a series of reports made by the investigators themselves—not easy reading but full of interesting new approaches and findings. Specially recommended are K. C. D. Hickman's chapter on vitamins for its understanding and as a masterpiece in the use of the King's English, Walter R. Miles's Psychological Aspects of Military Medicine, and the excellent illustrations of Detlev W. Bronk's Structure and Action of Nerve Cells.

Two other books should be mentioned in this category. *The Doctor's Job*, by Carl Binger, the reviewer reports, "is something different" for Dr. Binger "writes about medicine in the tradition of great physicians from Hippocrates to Osler." He helps both physician and patient to understand what the doctor's job is and how he gets it done. There is also *One Hundred Years of American Psychiatry*, the Centennial volume of the American Psychiatric Association. "Now everything about psychiatry in the United States and Europe during the last one hundred years is a matter of record—in a splendidly conceived and beautifully executed, readable historical document."

ENGINEERING AND ENVIRONMENTAL SANITATION

Drawing largely upon the studies carried out at the Cincinnati Station of the U. S. Public Health Service, Earle B. Phelps has written a book of timely interest in *Stream Sanitation*. He discusses in successive chapters the life history of a stream, the biology of growth and decay, the aerobic and anaerobic decomposition of sewage, the oxygen balance in polluted streams, and the public health aspects of bacterial pollution. His volume brings together in readable form a large amount of basic information otherwise available only from manifold published sources. A chapter on stream microbiology by the Senior Biologist of the Cincinnati Station, James B. Lackey, is included.

The second edition of *Mosquito Control—Practical Methods for Abatement of Disease Vectors and Pests*, by William B. Herms and Harold F. Gray, and published by the Commonwealth Fund, is an essential book for expert or novice in mosquito control work. The first edition, a comprehensive and practical handbook for public health and mosquito abatement officials, has

been revised and enlarged to include the new techniques of mosquito control which were rapidly developed during the war years.

"The recognition that in medicine as well as in politics and commerce, human relationships have expanded from the international into the global concept" is furnished by *Global Epidemiology*. The subtitle which the authors, Simmons, Whayne, Anderson, and Horack have given it, "*A Geography of Disease and Sanitation*," is more descriptive. This book started in the Medical Intelligence Division of the U. S. Army with the purpose of gathering information of value in planning the health protection and medical care of troops in whatever areas of the world stationed. Later the National Research Council proposed that the original surveys be published. It is an accomplishment worthy of praise to have brought together in orderly presentation this wealth of useful information gathered from diverse sources, many of which are not ordinarily accessible.

HEALTH EDUCATION

The Health Instruction Yearbook, edited by Oliver E. Byrd, succeeded well indeed in keeping "abreast of the rapidly changing developments and problems in public health, medicine and allied areas." It is not a manual of health education but "offers content and implementation for health instruction digested from current articles in public health and scientific journals." It is intended for public health educators, school health educators, nurses, students, and interested laymen.

Two reports from the Illinois Joint Committee on School Health, *A Basic Plan for Health Education and the School Health Program* and *A Basic Plan for Student Health and Health Education in Teacher Training Institutions*, illustrate the results of coopera-

tive labors such as have gone on in a number of states among workers in the fields of education, medicine and public health, and volunteer services. The Joint Committee represented 29 agencies. Approximately 100 persons served on the committees that prepared the different parts of these reports. "This wide participation is significant and should bring rich dividends in interest and leadership."

HOUSING

An Appraisal Method for Measuring the Quality of Housing, by the Committee on the Hygiene of Housing of the Association, makes available a new technique for inspecting and evaluating the health qualities of housing which is simple, objective, and susceptible to wide application. It is one of the major contributions to translating opinions into objective measurement in a most difficult field of appraisal. Every health officer should have it and should introduce it to his coworkers everywhere so that all agencies, public and private, should have the same units of measurement in their common purpose of eliminating slums, blighted areas, and substandard dwellings.

INDUSTRIAL HYGIENE

A fine book of special interest to many workers in public health is *Lead Poisoning*, by Abraham Cantarow and Max Trumper. The authors have brought together and coördinated the available data on this subject in a logical presentation and fine correlation of the material. There are a bibliography, index, and good cross-references. The volume is highly recommended to all those interested in occupational disease and industrial medicine. On the psychological side of industrial hygiene, May Smith's readable and well rounded *The Handbook of Industrial Psychology* "may well be considered required reading for the man who wants

to do more than issue orders." She boils down in small scope the entire panorama of problems besetting "those who are in some way responsible for others, or who have to get on with others." "There is not a line in her work, obviously the distillation of long research, which does not hew to the line of the common denominator, and which does not live up to its title, Handbook."

The Industrial Hygiene Section of the Association, through a Subcommittee on Chemical Methods, is responsible for the 41 page pamphlet *Methods for Determining Lead in Air and in Biological Materials*. Written by Professor J. Cholak, it reflects the vast experience that the Kettering Laboratory of the University of Cincinnati has had in the estimation of lead when present in minute quantities. This booklet is a valuable addition to the industrial hygienist's library. The bibliography is sufficiently complete so that additional details on any of the analytical methods can be obtained by those who are interested.

MEDICAL CARE

Late in 1944 the American Public Health Association adopted its official statement, Medical Care in a National Health Program (*A.J.P.H.* 34:12. (Dec.), 1944) which was hardly less forward looking and trailblazing than the President's Health Message a year later. Germane to this new impetus for a national medical care program is the Farm Foundation's *Medical Care and Health Services for Rural People*, which is a Report of the National Rural Health Conference in April, 1944. Record of a "milestone conference," this is an informal source book on virtually every aspect of the problem for those interested in equal health opportunity for our 57 million rural citizens. Rural shortages of doctors and hospitals are described vividly by those who

have experienced them. An active committee of farm organizations on rural health came out of this conference with a first goal of parity in health services with urban people.

The philosophy of medical care programs is discussed in Franz Goldmann's *Public Medical Care*. Dealing with public medical care as a social movement, it is a "masterful marshalling of material and highly stimulating." It should be interesting to all medical students and practising physicians, and is highly recommended to public health officers, hospital administrators and trustees and students of social security legislation.

MENTAL HYGIENE

"Some of the volumes in this field are discussed under History or under Medicine in War Time. Among others Stanley Cobb's *Borderlands of Psychiatry* explores a marginal area that has been despised and disputed territory. This borderland includes about 6,000,000 alcoholics, stammerers, epileptics, psychoneurotics, and others with neurological disorders. With his scientific approach, Dr. Cobb provides a clearer understanding about the millions dwelling in this border region. This book should be invaluable for those public health workers who wish to understand the people they serve. The reviewer slyly says "they will find it helpful even in understanding themselves."

Understanding emotional difficulties through a knowledge of their developmental components is the central theme of *Emotional Hygiene*, by Camilla M. Anderson. It is written in clear, simple language, enriched by illustrations from real life and lightened by appropriate veins of humor. It bears the stamp of a reverent and intellectually honest attitude toward those embarrassingly intimate mysteries of early personality development from which

later spring most of the inadequate emotional adjustments to life. To get the understanding contained in this volume into the popular thought stream becomes an important duty of public health workers.

MICROBIOLOGY

The third edition of Martin Frobisher's *Fundamentals of Bacteriology* was published in 1944 in an edition of 824 pages and 398 illustrations. It has been reorganized completely and has newly added material on penicillin, viruses, sulfonamide drugs, among others. Each chapter has a bibliography of recent material which not only covers the details of the text but should stimulate much wider reading. Both Dr. Frobisher and the publisher are to be congratulated on this "well groomed" textbook.

The Etiology, Diagnosis, and Treatment of Amebiasis, by Charles Franklin Craig, is timely because of the increased importance of amebiasis during and after the war. No one is better qualified than Colonel Craig to write on this subject. His book, well illustrated with photographs and line drawings, is in excellent format.

In *The Bacterial Cell*, René J. Dubos of the Harvard Medical School, reviews investigations in all relevant fields directed at the nature of the bacterial cell itself. His greatest contribution to the rapidly expanding field of bacteriology is a dynamic and analytic approach, outstanding examples of which are his chapters on staining properties and his discussion of virulence. This monograph is of peculiar value to investigators and students of bacteriology.

Sylvester Gould's *Trichinosis* is the first good monograph on trichinosis since that of Stäubli in German in 1909, and should be of value as a reference book. The excellence of the work leaves little opportunity for criticism.

An extensive bibliography covering the work of other authors during the period from 1822 to 1943 is included, as well as 128 excellently reproduced illustrations. The increased interest in the public health aspects of trichinosis makes this a timely volume.

Virus as Organism, by Frank McFarlane Burnet, is highly recommended reading. Here in Harvard University's *Monograph No. 8* of the Dunham Lectures for the promotion of medical science, a visitor from Australia has written a provocative book. He seeks to concentrate attention upon the broad concepts of epidemic disease in terms of the agent involved rather than in minutiae which at present are difficult to interpret. "As far as the doctor, the public health administrator and the biological experimenter are concerned, the pragmatic necessity will remain that virus be regarded as organism—self-reproaching, varying, and surviving like any other living being"—i.e., rather than as an inanimate, crystalline substance.

Of the second edition of Fred Wilbur Tanner's *The Microbiology of Foods*, Friend Lee Mickle says: "The public health official or student cannot afford to be without this exhaustive source of reference material on foods." The earlier book has been completely rewritten in painstaking and critical manner and expanded to include a wealth of material from the modern literature. Professor Tanner has fully accomplished his intention that this be a source book to the literature on foods as well as to methods of analysis. The material is well documented and well indexed in a volume attractively printed in readable type on good paper.

PENICILLIN AND OTHER ANTIBIOTICS

A noteworthy accomplishment of the war effort in relation to medicine has been the development of antibiotic therapy. This development is reflected

in a number of books that are valuable in crystallizing what is currently known about antibiotics even though that knowledge may soon be superseded by the findings of further researches. Among the books published in 1945 are Selman A. Waksman's *Microbial Antagonisms and Antibiotic Substances*, an authoritative and comprehensive survey of the subject developed historically and from the viewpoint of a soil microbiologist. He reviews the antagonistic activities of microorganisms with emphasis on their occurrence in nature and their relation to human, animal, and plant diseases, and discusses the chemistry and action of the known antibiotics and their application to the control of disease. The text is scholarly and unusually well documented. A bibliography of 1,016 references is appended. An excellent summary of available knowledge on the use of penicillin and other antibiotics in the treatment of human disease is included in John A. Kolmer's *Penicillin Therapy, Including Tyrothricin and Other Antibiotic Therapy*. It contains a good bibliography of original publications on the theoretical and practical aspects. It is a timely attempt to correlate the current information on penicillin and other antibiotic agents for the medical and dental professions. In a similar category is Wallace E. Herrell's *Penicillin and Other Antibiotic Agents*. In this the author has endeavored, in a concise and lucid text, to summarize the extensive fundamental and clinical studies in antibiotic agents. He divides his book into two parts—a historical survey and the clinical use of penicillin. Each chapter concludes with key references to the literature.

PUBLIC HEALTH ADMINISTRATION

The year has seen three significant volumes in public health administration. Together they form a complete trilogy for the administrator. Perhaps the

most important is Haven Emerson's *Local Health Units for the Nation*, which blueprints local health administration for the post-war years. Published by the Commonwealth Fund, which also provided the funds for the study, it is the result of a two year exploration by a subcommittee of the Association into the existing local public health framework and the organizational changes necessary to fit it into a proper vehicle for giving every person in every county of every state at least the basic minimum health protective services he has a right to expect from his local officers of government. The volume suggests that fewer than 1,200 health departments are needed if only the county instead of the town, township, or village, were the recognized administrative unit, if city and county joined in providing service for the entire county, and if thinly populated counties were to join with their neighbors to form a health district serving at least 50,000 persons. More full-time medically trained health officers, more public health nurses, greater professional leadership in public health engineering, dental and health education programs, better planning for laboratory service—all are needed and can be had on at least a minimum basis for one dollar per capita. The third edition of *Health Practice Indices*, by the Committee on Administrative Practice, presents the best yardstick yet devised for measuring the quality of performance of existing health departments. The third volume, Harry S. Mustard's *Government in Public Health*, is both historical and philosophic, and puts into proper perspective the thinking about the relation of government on various levels to the public health of the future. "One could hardly ask," says the reviewer, "for a more informative and thought provoking account of this increasingly important aspect of modern medicine."

PUBLIC HEALTH AND WAR

Whereas during the early years of the war, books in this classification were devoted largely to preparedness for war eventualities, the later ones that might be classified under this title either sum up the scientific advances made during the war or deal with problems of rehabilitation. Of the first type, the American Philosophical Society in 1944 published a *Symposium on Wartime Advances in Medicine*. In compact form this is an account of important medical advances made during the war. Competent authors cover the subjects of water requirements of castaways, blood derivatives and substitutes, penicillin treatment, advances in the treatment of wounds, immunization in wartime, human problems in military aviation, neuropsychiatry, and trends in the control of infectious diseases. This, with W. H. Taliaferro's *Medicine and the War* in 1944, and Morris Fishbein's *Doctors at War* in 1945, brings up to date, except for the post-war backward look, the interaction of war and medicine that was extensively explored in the 1942 symposium, *War Medicine*, edited by Winfield Scott Pugh.

Men Under Stress, by Roy Grinker and John Spiegel, is an "exceptionally well written book on the psychoneuroses precipitated by the stress of military life and aerial combat." "The style and terminology are such that the intelligent layman as well as the physician should be able to read and enjoy one of the most significant books to come out of the war." In *Psychiatry in Modern Warfare*, Edward A. Strecker and Kenneth E. Appel "have condensed a vast fund of information into a well documented and well written book." The nature of warfare in the two world wars is contrasted, and their potentialities as a cause of emotional disturbance, both among civilians and the armed forces. Half of the book is given over to Demobilization and the

Return to Civilian Life. This describes "the change in attitude, orientation, and behavior demanded of the military man when he returns home." There is an extensive and valuable bibliography. On a similar subject, George K. Pratt, Psychiatric Examiner at Induction Centers of the U. S. Armed Forces, in *Soldier to Civilian—Problems of Readjustment*, places primary emphasis "on a realistic recognition that a few neat packages of rules for dealing with the returned service man cannot be presented." What is good advice for one person may be the worst possible advice for another. There is also a valuable appendix on Community Services for Veterans.

PUBLIC HEALTH NURSING

In this field *Techniques of Supervision in Public Health Nursing*, by Ruth B. Freeman, published in 1944, is perhaps the most important. Her presentation of the philosophy and broad general principles of supervision and its tools is rooted in experience and is penetrating and comprehensive—together a masterly job which deserves recognition in wide and immediate use. Not so directly related to public health nursing but important, nevertheless, is Edith M. Stern's *The Attendant's Guide*, written in collaboration with Mary E. Corcoran and published by the wide-ranging Commonwealth Fund. It supplies, simply and clearly, information about the duties, attitudes, and knowledge expected of an attendant in a mental hospital. It should be read by student and graduate nurses entering the mental hospital for the first time because the knowledge about the behavior of the mentally ill and the conditions surrounding their care will make them better nurses.

TEXTBOOKS AND NEW EDITIONS

A number of standard works have been published in new editions, making

available the newer knowledge on the respective subjects. One of the most important, from the standpoint of the breadth of its influence at least, is the sixth edition of the Association's *The Control of Communicable Diseases*. This has literally gone around the globe with official imprints of 19 states, agencies and foreign countries, and in several languages, including Siamese. No public health worker should be without it. Another old friend is *Stitt's Diagnosis, Prevention and Treatment of Tropical Diseases*, edited in a seventh edition of two volumes by Richard P. Strong. "If," says the reviewer, "what is here so admirably presented were put to its logical and complete use by each physician as diagnostician and therapist and by the medical officers of civil and military authority, the face of the world would be immeasurably brightened from pole to pole." (This in spite of a number of proofreading errors also mentioned.) "Balance, sense of proportion, freedom from extreme or eccentric attitudes, fairness in presenting conflicting or opposite opinions, and data still disputed on matters of etiology, treatment, and epidemiology, characterize the text throughout."

Still another seventh edition is Asa C. Chandler's *Introduction to Parasitology, With Special Reference to the Parasites of Man*. Written primarily for college students, it is so complete and up-to-date that the medical and public health professions will find it of great value. Although the life cycle, anatomy, treatment, and prevention of parasitic forms are detailed, the broader problems of parasitic existence and general human implications of parasitic diseases are developed from Dr. Chandler's broad biological experience. The style is stimulating and readable.

Public health administrators who are finding it difficult to orient dental health within the field of public health should find enlightenment in the third edition

of *Bacterial Infection With Special Reference to Dental Practice*, by J. L. T. Appleton. "In the field of infection as in no other department of pathology or practice, medicine and dentistry meet on common ground." This book belongs on dental shelves also, for it offers the dentist a working guide in the field of infection.

There is also the second edition of the Association's *Diagnostic Procedures and Reagents: Technics for the Laboratory Diagnosis and Control of Communicable Diseases*. This has grown from a slender manual of microbiological laboratory science as applied to epidemiology to a mature and indispensable guide and reference book. Each of the sections is the well balanced and diligent work of highly qualified specialists whose basic scientific and technical knowledge is fully reflected in the treatment of the subject, and the references are critically selected.

Manual of Tropical Medicine, by Thomas T. Mackie, George W. Hunter, and C. Brooke Worth, was produced with the collaboration of the Army Medical School. It provides in an excellent manner a concise statement of the most recent available and authoritative information on tropical diseases. Its wide scope, clear exposition, and excellent illustrations place it in the forefront of the one-volume texts in this field.

Also in this category might be mentioned two year books for their usefulness as sources of varied information not easily obtainable elsewhere. The first is the *Municipal Year Book*, subtitled *The Authoritative Résumé of Activities and Statistical Data of American Cities*, and prepared annually by the International City Managers' Association. The 1945 authors are Clarence E. Ridley and Orin F. Nolting. Its intent is to supply "municipal officials with discussions of the current problems of cities, facts, and statistics

on city activities, and analyses of trends by population groups." Its annual public health summary brings together much interesting material on municipal public health matters, the 1945 data having featured city-county health units in the various states. The other is the *Social Work Year Book*, prepared annually by the Russell Sage Foundation under the editorship of Russell H. Kurtz and an advisory committee broadly representative of the various phases of health and welfare. The 1945 edition includes 75 topical articles discussed both historically and currently by 74 authors. Among the topics of most immediate interest to public health workers are Housing and City Planning, Maternal and Child Health, Medical Care, Mental Hygiene, Public Health, Public Health Nursing, Social and Health Work in the Schools, Social Hygiene, Social Insurance, and Tuberculosis. The directory, including a thumb-nail sketch, of national agencies—70 governmental and 402 voluntary—is also invaluable reference material.

TUBERCULOSIS

For tuberculosis workers, Dr. Max Pinner's *Pulmonary Tuberculosis in the Adult* is a "must" book. Among its special delights are extensive quotation from European literature; a critical attitude toward many conclusions and dogmas; a bibliography with extensive chapter references, a succinct statement of the author's main theme and often an evaluation of the work. He succeeds in his purpose "to create understanding, to form rational and consistent attitudes and approaches to the problem as a whole, to provide the basically necessary foundations on which the practical work should proceed." Ruth Puffer's *Family Susceptibility to Tuberculosis* is important in that it directs the attention of the health officer to a group often over-

looked in case finding, namely, siblings of the active tuberculosis sufferer, whether or not they live in the same household. *Mass Radiography of the Chest*, by Herman E. Hilleboe and Russell H. Morgan, covers all phases of mass x-ray surveys from the preliminary planning to the study and care of persons found to have x-ray evidence of pulmonary disease. The book should serve as an excellent reference source for public health workers.

The National Tuberculosis Association has continued its volumes on *Tuberculosis in the United States: Graphic Presentation*. In 1944 Volume 2 appeared "to provide a base-line for the study of changes in tuberculosis mortality by means of proportionate mortality," using the same basic material as the 1943 volume on mortality statistics in states and geographic divisions by age, sex and race. In 1945, Volume 3 presented the mortality statistics for large cities in the same detail. These studies are a practical contribution in the daily fight against the disease.

VITAL STATISTICS

Manual of Coding Causes of Illness According to a Diagnosis Code for Tabulating Morbidity Statistics, by the U. S. Public Health Service and the Bureau of the Census, "is the most important step so far made in our country towards responsible uniform comparable morbidity data." It will increase the "distinction and influence of the United States" at the next International Conference on Certified Causes of Death and Diseases to be held in 1948. It is "in as nearly perfect technical and textual form as possible, what all hopeful devotees of systematic morbidity reporting have awaited these many years." From the well known English statistician, R. A. Fisher, comes the standard classic for biological statistics, *Statistical Methods for Research*

Workers. Its simplified presentation is valuable not only to laboratory workers, but also to clinicians who would draw conclusions from any series of cases.

Another valuable reference book is *Handbook of Statistical Reference Data By District and Health Area 1931-1940*, compiled by Marjorie T. Bellows, Godias J. Drolet, and Harry Goode, and published by Neighborhood Health Development of New York. Although these are localized data (pertaining to New York City only), the volume gives health workers everywhere a clue to the kind of facts they must work with if they want to go about the task of improving community health intelligently and want to know whether they are getting results. Accurate diagnosis of health problems and application of correct remedies are based upon such data as are shown in this handbook.

VOLUNTARY HEALTH AGENCIES

The year 1945 produced two notable books dealing both historically and philosophically with voluntary agencies. The first to be published, Harold M. Cavins' *National Health Agencies*, extracts from dusty records and from the memories of the few who remain, with conciseness, vividness, and the human touch, the significant events in the

origins of 10 national health and four professional voluntary health organizations. Included are thumb-nail sketches of 82 national agencies interested, though not always exclusively in health. The second is one of the books that once in a generation start a movement that eventually radically changes the social architecture. *Voluntary Health Agencies*, by Selskar M. Gunn and Philip S. Platt, is the result of a three year study made under the auspices of the National Health Council under grants from the Rockefeller Foundation. It takes apart the national health agencies and their 20,000 local counterparts and suggests how their mechanisms could be integrated and coordinated to avoid the present results in many instances in "conflict between agencies, confusion of the public, an unbalanced community program and a deplorable lag in meeting emergent needs." It recommends the strengthening of the National Health Council for strategic planning among the national agencies, and on the local level, "one centralized, unified, voluntary health agency with one board and one executive, with special committees and staffs to direct the work of special divisions—tuberculosis, visiting nursing, mental hygiene, safety, etc."

Pulmonary Tuberculosis—By R. Y. Keers, M.D., and B.G. Rigden. Baltimore: Williams & Wilkins, 1945. 273 pp. illus. Price, \$5.00.

The authors have drawn on their experiences as medical staff members in English sanatoria to prepare this handbook for students and practitioners, and have brought together a very good clinical presentation of pulmonary tuberculosis. While the book is designed for the student and the general practitioner, it would also serve very well as a guide to the sanatorium physician.

English practice in the field of pulmonary tuberculosis as portrayed in this book is not strikingly different from American procedure.

The classification of tuberculosis used divides pulmonary tuberculosis as:

1. Primary Tuberculosis.
2. Post Primary Tuberculosis.
 - a. Haematogenous Dissemination.
 - b. Isolated Pulmonary Tuberculosis.

Reinfection, which term Americans would apply to Post Primary Tuberculosis, is a term the authors reserve for exogenous reinfection only and use

endogenous exacerbation to apply to lesions developing from endogenous sources rather than saying endogenous reinfection.

A short chapter at the end of the book on "Tuberculosis as a National Problem" seems all too brief. It would seem to have been highly desirable to bring the public health aspects of tuberculosis into the book earlier and more extensively as they relate to epidemiology and other phases of pulmonary tuberculosis so that the student and the practitioner might continuously have the public health and preventive viewpoint before them.

The American sanatorium physician will find the outline of sanatorium care of patients of definite interest.

BRUCE H. DOUGLAS

Men Without Guns—By DeWitt MacKenzie. *Captions by Major Clarence Worden. Foreword by Major General Norman T. Kirk. Philadelphia: Blakiston, 1945. Text 47 pp., 137 illus. Price, \$5.00.*

No more valiant contribution was made to victory in World War II than that of the men without guns, the officers and enlisted men of the Medical Department of the United States Army. This book is a literary and pictorial review of some of the most noteworthy of their achievements. It consists of 47 large pages of descriptive matter, divided into 8 sections, concerned with the medical corpsman; the doctor; actions in the Southwest Pacific, Saipan, Italy, Normandy, and the Burma Road; and rehabilitation of the wounded. This is followed by 137 paintings by a dozen artists, a collection sponsored by Abbott Laboratories. For each of these Major Worden has written exciting descriptive captions. The book, which is very well printed, is a fascinating review of the dangerous, heroic work of the medical officer and soldier. It should be of interest not only to medical veterans of

the World War, but to doctors, nurses, and veterans generally.

JAMES A. TOBEY

Hidden Hunger—By Icie G. Macy, Ph.D. and Harold H. Williams, Ph.D. Lancaster: Jaques Cattell Press, 1945. 286 pp. Price, \$3.00.

In spite of its sensational title and subtitle, this book is an accurate, semi-scientific presentation of a vast fund of information condensed into one volume.

The text differs from most books on nutrition in that it covers a much greater variety of topics than the majority of books of this kind. The wide range of subjects covered has necessarily precluded as thorough a treatment of many topics as might be desirable. Further, the frequent and lengthy quotations in fine print detract from the continuity of the central theme and effectivity of the book. However, it does bring into a single volume a diversity of information, which will be of value to those who are interested in the broad aspects of the field of nutrition.

The authors introduce a novel approach to the presentation of this kind of material by including accounts of the origin of this science, the founding of the different professional organizations, and scientific journals and the publication of some of the earliest texts concerned with nutrition.

The nutrients known to be essential for normal nutrition are considered, as is the malnutrition resulting from diets inadequate in these food constituents. The relationship of a variety of sciences, as bio-chemistry, physiology, medicine, etc., to nutrition is pointed out and the progress already made toward alleviating nutritional deficiencies is described.

Considerable space is devoted to the selection of foods and their uses; food habits, facts and fashions; fortification and enrichment; food preparation, preservation and processing; and food production, supply, and consumption. The

feeding practices of the Armed Services and industrial workers during World War II are discussed, as are the recommendations for adequate nutrition established by the White House Conference in 1930, the League of Nations, the 1941 National Nutrition Conference, and the Conference of the United Nations on Food and Agriculture. Some of the recent advances which should aid in promoting improved nutrition in the peoples of the future are described. The text is generously documented with references which add to the usefulness of the book for the general student.

ELSA ORENT KEILES

Annual Report of the Federal Security Agency. Section 4—U. S. Public Health Service—*Washington: Government Printing Office, 1945. 156 pp. Price, \$30.*

The U. S. Public Health Service, as everyone knows, has moved into new ground in the last decade, but it will surprise even the well informed to read this report and to appreciate its inclusiveness. The Surgeon General reports that during the war the nation's health did not lose ground but he maintains that "such passive maintenance of present health standards is not enough. In the peaceful years ahead, we must take up aggressively the task of improving the people's health."

Dr. Parran expects that during the reconversion period problems comparable in scope and extent with those of the war may be expected to arise. Among the recommendations of this report special emphasis is laid on building up all public health services with well trained personnel for every community in every part of the country; the addition of cancer control programs and dental care to traditional public health services; the establishment of mental health programs at the community level; the inclusion of bedside care as a part of the visiting services of all public

health nursing programs; and the continuation by states and communities of the environmental sanitation work which has been carried on during the war through federal appropriations. "It is now time," says Dr. Parran, "to set our sights for the broad objective—the attainment of complete health and medical service, of high quality, in all parts of the country. We must move forward rapidly toward this goal—doing more of what we have been doing and doing it better; shaking the dust out of our traditions; accepting the new . . ."

It is a wholesome experience to read this story of a dynamic service, and the experience should cancel out fears subtly planted that an expansion of the responsibilities of the Public Health Service is something to be dreaded.

REGINALD M. ATWATER

Textbook of Obstetrics—By *Henricus J. Stander, M.D. (3rd ed. rev.) New York: Appleton-Century, 1945. 1287 pp. 973 illus. Price, \$10.00.*

This handsome textbook represents the 9th edition of *William's Obstetrics*. Although this is Stander's third revision, it is the first time that the title page of William's has been changed to indicate the real author. Now it is as it should be, for the text is the obstetrics taught at Cornell where Stander is Professor of Obstetrics and Gynecology. The general plan of the book is new, with substitution of section and page headings for the traditional chapters.

Discussion of abnormal pelves and puerperal infection is unusually complete. Toxemia of pregnancy is well covered, but of course there is nothing new, except that "low reserve kidney" is just mentioned.

Stander has not been swayed by Watson's recent indictment of the Voorhees bag, nor impressed by Irving's experience in the management of abruptio placentae.

Cesarean section is thoroughly dis-

cussed. Cyclopropane and ethylene for anesthesia are preferred over local infiltration, and the safety of spinal anesthesia is said to be dubious. It is the practice at Cornell to sterilize the patient at the third cesarean section, though it appears that, at earlier operations, the patient's wish is of great importance.

Stander's book is excellent for students of obstetrics, whether undergraduates or specialists. It is highly recommended.

CHARLES A. GORDON

The Psychology of Seeing—By Herman F. Brandt, Ph.D. New York: Philosophical Library, 1945. 240 pp. Illus. Price, \$3.75.

The experimental findings in ocular photography of the Visual Research Laboratories, Drake University, Des Moines, Iowa, are reported in detail by the author, Professor of Applied Psychology and Director of the Laboratories. By means of a new bidimensional camera the eye movements of a subject are objectively recorded as dots (fixation points) on motion picture film which is subsequently projected on a field equivalent to the pages originally observed. An eye pattern, indicating the duration, location, and sequence of every fixation, as well as the distance, direction, and frequency of every excursion or eye movement, is thus established. A large body of repeated, controlled experiments on thousands of subjects has resulted in new evidence for the interpretation and evaluation of visual perception and of the working of the human mind.

More than half of the book is devoted to the application of these findings to the fields of advertising, learning, and art. The treatment, while interesting and suggestive, does not impress the reviewer as sufficiently convincing, despite the statistical techniques employed.

The chapter on "Projected Studies

and Their Applications" suggests the possibilities of ocular photography in measuring visual acuity, illumination effects, crime detection, personality, intoxication, aptitude, and efficiency. In spite of his enthusiastic belief in ocular photography as a scientific method of studying the human mind and its behavior the author asks acceptance only of such postulates as can be verified by painstaking research.

It is regrettable that the attention of the reader is so constantly distracted by the faulty typography and that so many of the 88 illustrations are wretchedly reproduced. The glossary and index are excellent.

PHILIP S. PLATT

Guide for Parents of a Preschool Blind Child—By Gertrude Van den Broek. New York: State Department of Social Welfare, Commission for the Blind, 1945. 48 pp.

The New York Commission for the Blind has maintained over a period of years a preschool service to parents of blind children. The experiences resulting from intensive study and training of preschool blind children in their home environment under the direction of Gertrude Van den Broek have been garnered by her and offered in a *Guide for Parents of a Preschool Blind Child*. The information given is expressed with rare sympathy, freedom from sentimentality, yet with complete scientific accuracy and soundness. Any parent, teacher, doctor, nurse, or older person in contact with blind children will have a keener interest in and a more assured and understanding approach to their needs after a thoughtful reading of this booklet. It is enriched by a final chapter "What to Expect of Your Child" from his first to his sixth year, and a list of books for both parents and children. This unique and welcome guide may be obtained from the Commission for the Blind, New York State Depart-

ment of Social Welfare, 205 East 42nd Street, New York 17, N. Y.

DOROTHY DEMING

Vapor Adsorption—By *Edward Ledoux*. Brooklyn, New York: Chemical Publishing Company, Inc., 1945. 360 pp. Price, \$8.50.

In this book literature on adsorption from widely scattered sources has been compiled and coordinated. Parts I and II deal with thermodynamics of air-vapor mixtures and with adsorption equilibria (static adsorption). These are prerequisites to a clear understanding of dynamic adsorption which follows in parts III and IV. Among important applications discussed in detail are dehydration of gases, particularly air, for comfort air conditioning, or for

industrial purposes by the use of silica gel or activated alumina. Absorption of water vapor with calcium chloride and condensation of vapors by refrigeration are also discussed as competing processes in special cases.

Separate chapters are devoted to conditioning of underground storage rooms and gas-proof shelters, drying of hygroscopic materials and optical instruments, dehydration of compressed air, and to recovery of vapors from air or other gases in process industries.

Although the book should appeal especially to chemical and air conditioning engineers, it should also be of value to industrial hygiene engineers who are concerned with removal of toxic, inflammable, or valuable gases from air of industrial rooms. C. P. YAGLOU

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Promising Foreshadow—In a huge sampling of the American population, the 1945 health record—aside from war losses—was excellent, the death rate being 2 per cent better than 1944. Expectation of life at birth is computed to be 65 years, a gain of 18 years in a third of a century.

ANON. War, Peace, and National Mortality. Stat. Bull. (Met. Life Ins. Co.), 27 1:1 (Jan.), 1946.

And Grim Reminder—Tuberculosis is still a major concern of public health even though the deaths dropped from a 5 year average of 60,000 per year to the middle 50,000's in 1944. The overall death rate declined 3 per cent from the 1943 rate but there were states in which whopping rises were reported.

ANON. Tuberculosis Mortality in Each State. 1944. Pub. Health Rep. 61, 5:144 (Feb. 1), 1946.

Pre-Atomic Records—How the 10 million casualties of the most destructive war (so far) are assumed to be divided among the belligerents constitutes dreadful evidence that aggression doesn't pay these days. The Germans are supposed to have suffered the greatest losses—3½ millions.

ANON. Military Deaths in World War II. Stat. Bull. (Met. Life Ins. Co.), 27, 1:6 (Jan.), 1946.

Public Un-Health—First hand account of France's "occupation disease," the result of famine, fatigue, deportation, pestilence, and filth, from the pen of a professor of medicine who survived them all. The country had little insulin, no glycerin or petrolatum, and all the physicians knew about penicillin was what they heard over the radio.

BESANCON, L. J. Public Health in France from the Invasion to the Liberation. War Medicine 8, 5:283 (Nov.-Dec.), 1945.

Topic for Controversy—If your particular job has any concern whatever with rheumatic fever, then you'll surely want to read these two lectures. If you have only a casual interest you'll find them formidable going. The term "rheumatic infection" may be a misnomer, for rheumatic fever may be a biochemical reaction of man, postulates the lecturer.

COBURN, A. F. The Rheumatic Fever Problem. *Am. J. Dis. Child.* 70, 5:339 (Nov.-Dec.), 1945.

"Let Us Not Be Weary of Well-Doing"—More evidence, if more is needed, that diphtheria immunization continues to pay extra dividends. With an epidemic producing a million cases a year in Continental Europe, England and the United States were spared, and in this country the rates were lowest where immunization was most nearly complete.

COLLINS, S. D. Diphtheria Incidence and Trends in Relation to Artificial Immunization, With Some Comparative Data for Scarlet Fever. *Pub. Health Rep.* 61, 7:203 (Feb. 15), 1946.

Is Influenza an Epidemiologic Brother to Measles?—In this not-to-be-missed paper, four points are discussed: agents which produce epidemics, possibilities in forecasting, survival between epidemics, and the mechanisms of periodicity. Even if it were possible, we would not attempt to epitomize the answers here. The jingle penned by Pope (Alexander, 1688-1744; not Alton).

"How index-learning turns no student pale
Yet holds the eel of science by the tail,"

cannot be applied to these annotations.

COMMISSION ON ACUTE RESPIRATORY DISEASES. The Periodicity of Influenza. *Am. J. Hyg.* 43, 1:29 (Jan.), 1946.

That Lingering Doubt—In a three county rural New York State district, 591 cases of poliomyelitis were studied. The results emphasized for the writers

that the accepted person-to-person mode of spread is based on weight of evidence, *but* some of the reported observations do not fit too well into the contact theory. The epidemiologists wish they might have had the benefit of a public health virus laboratory.

CONWAY, J. A., and BIGWOOD, D. E. Observations Made during a Poliomyelitis Epidemic in 1944 in the Hornell State Health District, New York. *New York State J. Med.* 46, 3:275 (Feb. 1), 1946.

Have We Schafered after False Gods?—Experience with two apneic patients casts serious doubt upon the efficacy of the Schafer method for producing artificial respiration. The tilting table method resulted in better ventilation of the lungs.

COMROE, J. H., and DRIPPS, R. D. Artificial Respiration. *J.A.M.A.* 130, 7:381 (Feb. 16), 1946.

Our British Brethren Face the Facts—Assuming that the British Labor Government will take away the hospitals and clinics from the public health officials, will there be anything left for them to do? Well, yes, concludes this M. O. H. after some dismal speculation. The public must not be led to believe that health depends on hospitals or doctors or bottles of medicine, he quotes (in effect). Sanitation, housing, freedom from industrial hazards, recreation and education are what count most. So, the aggrieved health officer will still have plenty to do to keep him out of mischief whatever His Majesty's Government puts over on him.

JERVIS, J. J. Has Public Health Any Future? *Pub. Health* 59, 4:46 (Jan.), 1946.

More Polio Research—There is room for two schools of thought, assert these writers, one postulating the transmission of poliomyelitis exclusively through human contact, the other holding that extra-human reservoirs of virus exist. Though these researchers have

delved diligently into the possibility of animal vectors—their present work was concerned with house mice—they are led to the conclusion that evidence favors the direct human transmission of the disease.

JUNGEBLUT, C. W., and DALLDORF, G. Epidemiological and Experimental Observation of Poliomyelitis in New York City, (1943-1944). *Am. J. Hyg.* 43, 1:49 (Jan.), 1946.

Not Copyrighted—Of bright new British coinage is the appellation, "indoor storms" for the pollution of confined air with invisible showers of germs—sneezed and coughed. There is little new in the article about the prevention of spread of indoor infection except the very original title. Incidentally, administrators hereabouts would be mildly amused by this number of the *Health Educational Journal* if they could see it. The first paper entitled "Health Education" covers such divers matters as dental, prenatal, and mental hygiene clinics, social medicine, and mass feedings. Bemused administrators may wonder what is left in the whole field of public hygiene when the health educator is done.

MITMAN, M. Indoor Storms. *Health Educ. J.* 4, 1:21 (Jan.), 1946.

Dental Note—If lactobacilli and acidogenic cocci break down carbohydrates to destroy tooth enamel, then why not immunize the body against these germs? Repeated injections of vaccines made of these organisms were given to rats with what effect, do you suppose, on the numbers of the same germs found in the crypts of the rat's teeth? This time we'll save you trouble: the vaccines did not discourage the bacteria.

PARSONS, E. L., et al. The Effect of Immunization against Lactobacilli and Acido-

genic Cocci on the Tooth Flora of the Rat. *Am. J. Hyg.* 43, 1:41 (Jan.), 1946.

It's High Time Department—If motion pictures have a place in mental hygiene, as this report upon military experience suggests, then films most certainly have an educational job to do in the other fields of public health, a job which—so far as I know—is being ignored masterfully by most established health agencies.

ROME, H. P. Motion Pictures as a Medium of Education. *Ment. Hyg.* 30, 1:9 (Jan.), 1946.

Child Health from the Business End—Herein is reported a British study of problem mothers, a problem mother being one who gives her children less than minimal care and refuses to cooperate with professional guidance. There were 89 among 7,215 families with one or more pre- or elementary school children. The children who survived this maternal neglect were discovered to be lousy, ill-fed, and retarded in school, and it was found further that the infant mortality rate was directly related to the intelligence of the mothers.

SAVAGE, S. W. Intelligence and Infant Mortality in Problem Families. *Brit. M. J.* 4437:86 (Jan. 19), 1946.

Good Red Blood—Our recent preoccupation with vitamins and minerals has tended to overshadow the subject of proteins. Now that good sources of protein foods are in short supply we begin—happily—to take a renewed interest in the factor which has so much to do with maintaining health. Three papers discuss in turn, clinical aspects, methods of securing high protein diets, and the use of food yeast as a supplement.

TUI, C. Some Clinical Aspects of Protein Nutrition (and two related papers). *J. Am. Dietet. A.* 22, 2:97 (Feb.), 1946.

BOOKS RECEIVED

- THE ABC'S OF PUBLIC RELATIONS FOR RECREATION.** A Primer for the Recreation Worker. New York: National Recreation Assn., 1946. 64 pp. Price, \$85.
- AN INTRODUCTION TO ESSENTIAL HYPERTENSION.** By Richard F. Herndon, M.D. Springfield, Ill.: Thomas, 1946. 88 pp. Price, \$2.50.
- BETTER HEALTH FOR RURAL AMERICA.** Plans for Action for Farm Communities. Inter-bureau Committee on Post-War Programs, U. S. Dept. of Agriculture. Washington, D. C.: Gov. Ptg. Office, 1945. 34 pp. Price, \$20.
- BURMA SURGEON RETURNS.** By Gordon S. Seagrave, M.D. New York: Norton, 1946. 268 pp. Price, \$3.00.

ASSOCIATION NEWS

SEVENTY-FOURTH ANNUAL MEETING AMERICAN PUBLIC HEALTH ASSOCIATION CLEVELAND, OHIO — NOVEMBER 12-14

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- M. Leon Bauman, M.D., 1505 Linwood, Parsons, Kans., Health Officer, Labette County Health Dept.
- Burke Brewster, M.D., City Hall, Fort Worth, Tex., Director, Dept. of Public Health and Welfare
- Choi Chang Soon, M.D., School of Public Health, Ann Arbor, Mich., Health Officer, Bureau of Public Health, Government of Korea
- Raymond H. Curry, M.D., Cabell County Health Officer, Barboursville, W. Va.
- Charles F. Dotto, 88 Mount Pleasant Ave., West Orange, N. J., Health Officer, Township of Maplewood
- Morley R. Elliott, M.D., D.P.H., 320 Sherbrook St., Winnipeg, Man., Canada, Director, Division of Extension Health Services, Dept. of Health and Public Welfare
- Pum Suk Han, M.D., 808 E. Catherine, Ann Arbor, Mich., Health Officer, Bureau of Public Health, Government of Korea
- Eglon Malta-Santos, M.D., 527 Church, Ann Arbor, Mich., Asst. to Para Sector Director of the Amazon Program, Servico Especial de Saude Publica, Brazil
- John Sinclear McCannel, M.D., C.M., 14 Pinehill Rd., Toronto, Ont., Canada, Student, School of Hygiene, Univ. of Toronto (to be Medical Officer of Health)
- Dr. Augusto Morales-Asua, 811 E. Catherine, Ann Arbor, Mich., Student, Univ. of Mich., School of Public Health (Rockefeller Foundation Physician in Bolivia)
- Joseph L. P. Richard, M.D., 147 Victoria St., Edmundston, N.B., Canada, District Medical Health Officer

- Conrad E. Rosdahl, M.D., Kittitas County Health Dept., Ellensburg, Wash., Health Officer
- Dr. Jose Saralegui-Padron, 216 N. State St., Ann Arbor, Mich., Student, Univ. of Mich., School of Public Health (Director of Health Center in Uruguay)
- Bernard Sternhill, M.D., 1951½ New Jersey St., Los Angeles 33, Calif., Base Surgeon, AAAF, Alexandria, La.
- Bertha E. Stokes, M.D., Ascension Parish Health Unit, Donaldsonville, La., Director
- Guillermo Vasquez, M.D., M.P.H., 126 Kirkman St., Lake Charles, La., Director, Calcasieu-Lake Charles Health Unit
- Hugh W. Ward, M.D., Prince Frederick, Md., Deputy State Health Officer
- John S. Wheeler, M.D., M.P.H., 17 School St., Concord, N. H., State Health Officer

Laboratory Section

- Estella Alevy, 5421 Sierra Vista Ave., Hollywood 38, Calif., Student, Univ. of California
- Edward A. Birge, M.D., State Laboratory of Hygiene, Madison 6, Wis., Asst. Professor of Clinical Pathology
- Phyllis Conner, Mt. Sinai Hospital, Chicago 8, Ill., Bacteriologist
- Jaroslav Drbohlav, M.D., D.P.H., Mysliveckova 8, Prague, XIV, Czechoslovakia, Director, Div. of Diagnosis, Czechoslovak National Institute of Health
- Nathan Entner, 2246 Malcolm Ave., Los Angeles 25, Calif., Student, Univ. of California
- Vernon D. Foltz, M.S., Kansas State College, Dept. Bact., Manhattan, Kans., Assoc. Professor of Bacteriology

Bernard Heinemann, Ph.D., 3593 Bainbridge Ave., New York 67, N. Y., Research Bacteriologist, Schieffelin & Co.

Emmarie C. Hemphill, M.A., 1005 Berkshire, Ann Arbor, Mich., Assoc. Serologist, Bureau of Laboratories, Texas State Dept. of Health

George R. Lacy, M.D., Dept. of Public Health Laboratory, Municipal Hospital, Pittsburgh, Pa., Director of Laboratories

LaRue, Roesling, 1127 E. Ann St., Apt. 28, Ann Arbor, Mich., Working in Laboratory, St. Joseph's Mercy Hospital

Dr. A. Ch. Ruys, Honthorstraat 50B, Amsterdam, Z, Holland, Professor of Bacteriology, Univ. of Amsterdam

Gerald J. Schipper, M.D., 903 Cathedral St., Baltimore, Md., Student, Johns Hopkins School of Hygiene and Public Health

HOWARD M. KLINE, PH.D., APPOINTED
TECHNICAL SECRETARY FOR MEDICAL
CARE STUDIES

The Executive Board of the American Public Health Association, on recommendation of the Subcommittee on Medical Care, Committee on Administrative Practice, has appointed Howard M. Kline, Ph.D., of Washington, D. C., as technical secretary to head a staff to conduct studies under the direction of the committee.

It will be recalled that the Rockefeller Foundation, through the International Health Division, has recently made an appropriation to the Subcommittee on Medical Care for studies of existing programs, especially in relationship to health departments, and for the analysis of pending legislation (*A.J.P.H.* Mar. 1946, p. 302).

Dr. Kline, who is a native of Covington, Kentucky, is a graduate of the University of Toledo and holds the A.M. and Ph.D. degrees from the Maxwell School of Citizenship and Public Affairs, Syracuse University. His specialty in academic life was public law and public administration. He served on the instructional staff of Syracuse University, the University of Michigan, and the University of New Mexico, and was assistant professor of public law and public administration at the University of Maryland. For two years ending in 1944 Dr. Kline was chief of the State Consulting Service, Division of Vital Statistics, U. S. Bureau of the Census, Washington. Since January, 1944, he has been a commissioned officer in the

U. S. Public Health Service detailed by the Division of Public Health Methods to Procurement and Assignment Service of the War Manpower Commission, more recently attached to the Office of the Administrator, Federal Security Agency.

Howard M. Kline

In this capacity he served as chief of the field and of the statistics sections, as assistant executive officer, and has most recently been serving as acting executive officer of the Procurement and Assignment Service.

Serving with Dr. Kline will be two staff associates whose appointments will be announced shortly.

LETTER TO THE EDITOR

SIR:

I note with much interest, the article by Dr. Edith Potter on the Rh factor in the current Journal, as well as your editorial comment.

You may be interested to know that since 1944, the Paterson Board of Health Laboratories, at the request of the Passaic County Medical Society, have tested every prenatal specimen of blood received by us for the Wassermann test, for the Rh factor and blood grouping as well. I am enclosing a reprint describing the results of the first year of our work. (*J.A.M.A.*, May 5, 1945, Vol. 128, p. 19.) As far as I know, we are the first municipal laboratory to enter this field.

I wish I could agree with the comment on the simplicity of the test. Like all serological tests, it must be carefully handled by experienced serologists. Many are the crimes committed in the name of Rh by the inexperienced technician. Then, too, all Rh is not divided into two parts of which one shall be clearly Rh-positive and the other Rh-negative. The sub-type rears its head, etc.

I congratulate you on having secured so eminent an authority as Dr. Potter to write that fine article.

ANNA I. VAN SAUN,
Director

Paterson, N. J.

EMPLOYMENT SERVICE

The following pages present information for those seeking qualified public health personnel and for those seeking positions in public health.

This is a service of the Association conducted without expense to the employer or employee.

Address all correspondence to the Employment Service, A.P.H.A., 1790 Broadway, New York 19, N. Y., unless otherwise specified.

Vacant Positions Listed with the Association's Vocational Counseling and Placement Service

A considerable number of additional openings for candidates trained in the various public health specialties have come to the attention of the American Public Health Association's Vocational Counseling and Placement Service during the past month. At the time this issue of the *Journal* goes to press the number of all available openings listed has increased to 412 positions offered by 122 employers in more than 30 states and territories. The openings are in official agencies on local, state, and federal levels, as well as in voluntary health agencies and in a few industrial companies.

Two hundred forty openings—58 per cent of the total number—were offered to physicians for positions carrying administrative, epidemiologic, and (more infrequently) clinical responsibilities. Eighty-two positions were listed for sanitary engineers and sanitarians, 5 for industrial engineers, 11 for non-medical administrators, 7 for dentists, 27 for health educators, 24 for laboratory workers, 5 for statisticians, and 11 for allied professional groups.

One hundred forty-three trained candidates in the various professional categories have recently indicated their interest in public health positions and have filed or reactivated their applications for registration with our Placement Service; a great percentage of them are veterans of the armed forces or expect their release in the near future. Candidates for openings in the field of public health nursing are not registered but are being referred to professional placement agencies for clearance.

The Vocational Counseling and Placement Service is jointly sponsored by the American Public Health Association's Committee on Professional Education and the U. S. Public Health Service. It offers free assistance to all employers and trained candidates for positions in the public health field and trained specialists available for counsel by personal contact and correspondence with all men and women who are interested in public health work.

POSITIONS AVAILABLE

(Supplemental to list in March Journal)

Wanted: Director, State-wide Hospital Survey. Survey of hospital facilities in Maryland planned under special committee of State Planning Commission. Chicago, Illinois—Marine Hospital, 4141 Clarendon Avenue.....	May 31

The oral professional, academic, and physical examinations will be held at 9 A.M. at places and dates given above. The final written portion of the examination will be given simultaneously at the above locations beginning on June 5, 1946, and ending on June 7, 1946. The written portion of the examination may be given at certain other stations of the Service where two or more regular commissioned officers are on duty, if request is made by an applicant. Minimum age—21.

Education and Training: (1) Assistant, at least 7 years of educational (exclusive of high school) and professional training or experience and a degree in engineering (sanitary engineering course); (2) Senior Assistant, as above plus 4 additional years of post-graduate professional training or experience.

Compensation (including allowance for quarters and subsistence): (1) Assistant, \$3,411.00 with, and \$2,975.50 without dependents; (2) Senior Assistant \$3,991.00 with, and \$3,555.50 without dependents.

Applicants should address a letter to the Surgeon General, U. S. Public Health Service, Washington, D. C., at the earliest practicable date, requesting application blanks. Such letter should include a brief biographical statement relative to professional school or college attended, type of studies pursued, degrees granted and subsequent training or experience. Applicants of foreign birth must furnish proof of United States citizenship.

Transportation expenses to and from and cost of maintenance at place of examination must be assumed by the candidate.

Announcement of Scholarships in Nutrition

Four scholarships available, through North Carolina State Board of Health, at University of Tennessee, Knoxville, for year 1946. Applicants can enter in March or June. Scholarships will provide stipend of \$100 a month for 12 months plus tuition fees and travel while in training. Training period will be for 12 months and will include 9 months' formal training and 3 months' supervised field work. Eligibility requirements: (a) Age between 23 and 35 years; (b) Bachelor's degree in foods and nutrition, chemistry or biological sciences from a recognized institution; (c) teaching, hospital dietetics, nutrition research or other related subjects for a period of at least 2 years. Upon successful completion of training at University of Tennessee, candidates will be employed as nutritionists by North Carolina State Board of Health. Salary scale for nutritionists is \$1,800 to \$3,000 with additional travel allowance of \$1,200 a year. Interested applicants should send transcript of their college record and statement of experience since graduation to Director of Nutrition Division, State Board of Health, Raleigh, N. C.

WANTED—(a) Public health physician to serve as medical associate on staff of national health agency; duties include program planning, writing, speaking, and travel; headquarters in New York. (b) Professor and head of department of Hygiene; state university planning extension program and offering curriculum in Public Health whereby students may major and receive baccalaureate degree; young man experienced in teaching qualified to develop program required. (c) Director of communicable disease division; central metropolis; ex-service man who wishes a career in public health work preferred; Middle West. (d) Woman physician to take charge of medical department of progressive day school connected with university; approximately 800 children from 4 to 16; ninety from 2 to 4. (e) Public health physician with administrative experience or ability to direct department serving town of 45,000; progressive program, well staffed department; South. (f) Assistant health officer, preferably tuberculosis clinician with public health experience; town of 40,000 in Southern California; \$4,500 including travel expenses. (g) County health officer; in-service training provided; woman eligible; minimum \$4,200, clinician, venereal disease control program; \$4,500; South. (h) Woman physician to succeed director of student health department in young women's college; enrollment approximately 1,300 students; 200 faculty; medical staff comprised of four full-time physicians and consultant psychiatrist; modern infirmary with well equipped x-ray and laboratory department; faculty appointment with full voting privilege. (i) County health officer; winter resort town; \$5,000-\$5,700, including travel expense; South. **PH4-1** The Medical Bureau, Burneice Larson, Director, Palmolive Building, Chicago 11.

WANTED—(a) Health coordinator; small community in Wisconsin; well organized program. (b) Health educator; private, non-profit agency providing medical care and health services to large group of workers; Master's degree in education with major in health education desirable; \$3,600 plus travel allowance. (b) Health educator; public school system; Southwest; immediately. (c) Health educator; tuberculosis agency; East. **PH4-2** The Medical Bureau, Burneice Larson, Director, Palmolive Building, Chicago 11.

WANTED—(a) Public health supervisor; county department of health; Southern California. (b) Several public health nurses; considerable travelling; good climate, roads and opportunity for advancement; winter resort area of the South. (c) Instructor in health; state teachers' college; duties consist of serving as nurse instructor in department of health of college and working with physicians in student health department; East. (d) Public health nurse qualified in tuberculosis nursing to supervise tuberculosis program; county health department; possibility of clinic being developed as research unit; East. (e) Several public health nurses; in-service training provided during which time salary will be \$135 monthly; South. (f) Clinic nurse; county health department; public health certificate necessary; Washington State. Executive director, visiting nurse association; small organization; interesting expansion plans; will have opportunity of selecting own workers; \$3,000; car provided; town of 150,000; Middle West. **PH1-3** The Medical Bureau, Burneice Larson, Director, Palmolive Building, Chicago 11.

*Advertisement***Opportunities Wanted**

Administrator—Military officer of high rank is available for administrative position in public health; trained in public health before entering Army; considered one of the outstanding commanders of general hospitals; leaders in military and civilian hospital and medical fields unite in recommending him as outstanding administrator, well able to serve as administrator for metropolitan city or large area; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Dentist, Veteran World War II; certificate from Forsyth Infirmary for Children; several years, public health experience and two years' private practice before joining Armed Forces; available immediately; for further information, please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

Health educator; Master of Science degree in public health; thorough knowledge in general public health (administration, biostatistics, epidemiology, industrial hygiene, dental hygiene, tuberculosis and venereal disease control, etc.) and in principles, methods and functions of public health education; record of interesting administrative experience; for further information please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Public health nurse; B.S. degree with major in public health nursing; professionally trained in university school of nursing; five years' supervising experience in public health; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

NEWS FROM THE FIELD

INTERNATIONAL ACTION IN THE FIELD OF PUBLIC HEALTH

The Economic and Social Council of the United Nations has recently adopted a resolution regarding an International Health Conference. A meeting of a technical preparatory committee was called to meet in Paris, France, not later than March 15, and instructions were given to call the conference of the United Nations to consider the scope of and the appropriate machinery for international action in the field of public health not later than June 20, 1946, at a place to be fixed in consultation with the President of the Economic and Social Council.

Experts from 17 different countries are to attend the meeting of the preparatory committee. Thomas Parran, M.D., Surgeon General of the U. S. Public Health Service, has been designated the United States Expert and James A. Doull, M.D., Medical Director, U. S. Public Health Service, has been designated alternate. Drs. Parran and Doull were expected to leave Washington on March 15 for the meeting. The resolution follows:

The Economic and Social Council, taking note of the Declaration proposed by the Delegations of China and Brazil at San Francisco and unanimously approved regarding an international health conference, and recognizing the urgent need for international action in the field of public health,

1. Decides to call a Conference of the United Nations to consider the scope of, and the appropriate machinery for, international action in the field of public health and the proposals for the establishment of a single international health organization of the United Nations;

2. Urges the Members of the United Nations to send as representatives to this Conference experts in public health;

3. Establishes a technical Preparatory Committee to prepare draft annotated agenda and proposals for consideration of the Conference, and appoints the following experts or their alternates to constitute the Committee;

4. Directs the Technical Preparatory Committee to meet in Paris not later than March 15th and to submit its annotated agenda and proposals to the members of the United Nations and to the Council not later than May 1st.

5. Decides that any observations it may make at its second session on the report of the Technical Preparatory Committee will be communicated to the proposed international Conference.

6. Instructs the Secretary General to call the Conference not later than June 20th, 1946, at a place to be fixed in consultation with the President of the Economic and Social Council.

DR. STEBBINS RESIGNS AS NEW YORK CITY COMMISSIONER OF HEALTH

The resignation of Ernest L. Stebbins, M.D., M.P.H., who has been Commissioner of Health of New York City since July 15, 1942, was announced March 4 by Mayor O'Dwyer, who at once appointed Edward M. Bernecker, M.D., as Commissioner of Health to succeed Dr. Stebbins.

Dr. Stebbins when appointed was Professor of Epidemiology at the Columbia University School of Public Health, New York City, having previously served on the staff of the New York State Department of Health in several capacities, and in Virginia as a county health officer. Dr. Stebbins is a graduate of Rush Medical College in

Chicago in 1930, and holds the M.P.H. from Johns Hopkins University School of Hygiene and Public Health. His appointment as Professor of Public Health Administration at Johns Hopkins has been announced effective July 1, 1946, when he will succeed Allen W. Freeman, M.D., on his retirement.

Dr. Bernecker was born in 1892, and is a graduate of the Hahnemann Medical College and Hospital, Chicago, 1915. He has served with the New York Department of Hospitals for about 30 years, having served as Commissioner of Hospitals since 1942. Dr. Bernecker's successor as Superintendent of Hospitals is William F. Jacobs, M.D., who has been Medical Superintendent of Bellevue Hospital, New York City.

VOLUNTARY MEDICAL CARE PLAN OF AMERICAN MEDICAL ASSOCIATION

According to an announcement dated February 16, 1946, the American Medical Association is developing a country-wide system of voluntary sickness insurance protection to be operated on a non-profit basis by local medical groups. Details of the program will be worked out and administered by a director and staff of a newly created Division of Prepayment Medical Care Plans of the Association.

Four standards of acceptance by the American Medical Association Council on Medical Care for voluntary prepayment medical and hospital care plans were adopted as follows:

1. Approval of the state or county medical society in the area in which they operate
2. Responsibility for the medical services included in the benefits assumed by the medical profession in the area
3. Free choice of a qualified physician and maintenance of personal confidential relationship between patient and doctor
4. Operation to provide the greatest possible benefits in medical care to subscribers

Details of the program were announced in the *J.A.M.A.* for Feb. 23.

It has already been determined that premiums may vary in different parts of the country; nor need method of paying benefits be uniform; they might be in terms of either cash indemnity or in units of medical service.

A subsidiary organization, Associated Medical Care Plans Inc., made up of participating insurance groups, will undertake to establish coördination and reciprocity among the various local plans to permit transference of subscribers from one plan to another and use of benefits in any state in which a subscriber happens to be located. This subsidiary group will undertake research, compile statistics on medical care, provide consultation and information on existing plans, and sponsor an educational program to acquaint the public with the voluntary insurance program.

ROCKEFELLER FOUNDATION GRANTS \$78,500 FOR COÖRDINATION OF VOLUNTARY HEALTH AGENCIES

To support a program of coördinating the 20,000 voluntary health agencies of the country, the Rockefeller Foundation has granted \$78,500 to the National Health Council, New York, N. Y., with which the Council, under the leadership of a Citizens' Planning Committee and an outstanding new director to be selected, plans facilities for joint planning, joint activities and services for the national agencies, the organization of new and the strengthening of established local health councils, and a counselling field service to local agencies. Demonstrations in the co-ordination of local health agencies will be carried on, as well as coöperation with Community Chests and Councils in unified fund-raising campaigns for those national health agencies wishing to join in a United effort.

Commenting on the Foundation's grant, Eleanor Brown Merrill, President of the National Health Council,

said "The grant presents a great opportunity to accomplish needed coördination in the whole voluntary field. The Council will be able to assume the dynamic leadership for which the national situation, as well as the local agencies, have been calling. There are few projects which should have a more constructive effect upon the future health of the American people."

A Rockefeller Foundation grant made possible the establishment of the National Health Council in 1921. It also financed the 4 year Gunn-Platt study, the report of which, *Voluntary Health Agencies*, was published in September, 1945. In focusing attention upon the unevenness and weakness in the accomplishment of many local agencies it has already stimulated a number to appraise their work and to seek guidance and counsel. The new program of the National Health Council will make it possible to provide consultation services.

ANNIE WARBURTON GOODRICH—80 YEARS

To mark her 80th birthday, the *American Journal of Nursing* and four hundred leaders in nursing, public health, science and medicine honored Annie W. Goodrich with a luncheon in New York on February 26. A handsome brochure summarized her achievements, beginning in 1893, when she became Superintendent of Nurses of New York Post-Graduate Hospital down to 1934, when she retired as Dean of the Yale University Nursing School which she had organized in 1923. In the years between she had been Superintendent of Nurses at St. Luke's and New York Hospitals, taught at Teachers College, headed the Nurse Training School of Bellevue Hospital, inspected nurse training schools for the New York State Department of Education, directed the Henry Street Visiting Nurse Service, and organized the Army School of Nursing during the first World War.

She has studied nursing conditions in both Europe and the Orient, holds numerous honorary degrees, and has been awarded the Medaille d'Honneur de l'Hygiene Publique and the Silver Medal of the Ministry of Social Welfare by France. At present she is a member of the Board of Nursing Advisors of the Yale Institute of Living.

Among those who signalized her contributions to nursing education and nursing service were Professor C.-E. A. Winslow, Dean Alonzo Curran of the Long Island College of Medicine, John H. Hayes, President Elect of the American Hospital Association, and Mary Elizabeth Tennant of the Rockefeller Foundation. Pearl McIver presided.

Dr. William P. Shepard, on behalf of the American Public Health Association and its Committee on Professional Education sent greetings:

"Please accept congratulations on your many years of outstanding service to professional education in general and to nursing education in particular. It is amazing to reflect on the progress of nursing in the span of your lifetime. It is a privilege to tell you how much we appreciate your many valuable and lasting contributions to this progress. We who are interested in attracting superior people to the public health field and in making public health careers more attractive salute you and gratefully acknowledge your achievement and assistance."

\$200,000 FOR TROPICAL DISEASE RESEARCH

The Department of Public Health and Preventive Medicine of Cornell University Medical College has begun a ten year program of research in the "immunologic and allergic manifestations of exotic disease, and to provide for a better understanding of their prevention and treatment in relation to other allergic diseases." This study is made possible by a grant of \$20,000 annually for ten years from the Marcelle Fleischmann Foundation, organized by E. M. Fleischmann of Baltimore in

memory of his wife. The Foundation is interested primarily in allergic diseases and their various manifestations.

Wilson G. Smillie, M.D., Director of the Department of Public Health and Preventive Medicine, in announcing the grant early in 1946, reported that research was already under way, under the leadership of Dr. Morton C. Kahn, Associate Professor of Public Health and Preventive Medicine, assisted by a staff of five. Such fields as malaria, filaria, and the schistosomes will be investigated.

CLEVELAND MUSEUM IN A NEW HOME

The February *Museum News* of the Cleveland Health Museum announces that its new home is being prepared for Spring occupancy. Three doors from the present location, the new building will provide for the expanding services of the Museum. Floor plans show how the building will be utilized for exhibits, classrooms, lecture halls, and other purposes.

FRIEND LEE MICKLE HONORED FOR TWENTY-FIVE YEARS OF SERVICE

Friend Lee Mickle, Sc.D., was recently honored by his associates in the Bureau of Laboratories, Connecticut State Department of Health, Hartford, in recognition of the completion of 25 years of service as Director of the Bureau. A gold wrist watch was presented to him by Earl K. Borman, Assistant Director of the Laboratory, on behalf of his colleagues. Dr. Mickle, formerly a member of the Executive Board, A.P.H.A., and Chairman of the Laboratory Section, is now Chairman of the Standard Methods Committee for Frozen Desserts and Ingredients.

AMERICAN PUBLIC HEALTH EXPERTS CALLED TO TOKYO

The authorities in charge of public health in Japan have announced that John R. Paul, M.D., Professor of Preventive Medicine at Yale University

School of Medicine, New Haven, and W. D. Hammon, M.D., Associate Professor of Epidemiology at George Williams Hooper Foundation, University of California, San Francisco, arrived on March 1 in response to an invitation to them to study the prevailing Japanese encephalitis and measures which may be used to prevent its spread to the occupying forces.

LUCILE PETRY BECOMES CHIEF, DIVISION OF NURSING, U. S. PUBLIC HEALTH SERVICE

The appointment of Miss Lucile Petry, who recently has been head of the U. S. Cadet Nurse Corps, as Chief of the new Division of Nursing of the U. S. Public Health Service, has been announced by Dr. Thomas Parran, Surgeon General. She will rank as Nurse Director while serving as chief of a division. Miss Petry joined the Public Health Service in 1941 as nursing consultant and became director of the Cadet Nurse Corps in July, 1943. She is a graduate of the University of Delaware and of Johns Hopkins School of Nursing, and holds a Master's degree from Columbia University Teachers College.

According to Dr. Parran, the Division of Nursing in addition to being responsible for administration of the Cadet Nurse Corps will coördinate all nursing activities of the Public Health Service. It is a recognition of the great importance of nursing activities as part of the total health program. The responsibilities of the division will include public health nursing, hospital nursing, and nurse education. The senior assistants to Miss Petry will include Pearl McIver, R.N., Jessie MacFarlane, R.N., Minnie E. Pohe, R.N., Claire H. Favreau, R.N., and Mary J. Dunn, R.N.

HERMANN M. BIGGS MEMORIAL LECTURES The New York Academy of Medicine

has announced that the Hermann M. Biggs Memorial Lecture which is held annually in Hosack Hall at the New York Academy of Medicine under the auspices of the Committee on Public Health Relations will be delivered this year on Thursday, April 4 at 8.30 P.M. by Laurence H. Snyder, Sc.D., Professor of Medical Genetics, Department of Medicine, Ohio State University.

The subject of the lecture will be "Medical Genetics and Public Health."

This lecture is open to the general public.

MASSACHUSETTS PUBLIC HEALTH ASSOCIATION OFFICERS FOR 1946

President, Charles F. Wilinsky, M.D., Boston
1st Vice-President, Vlado A. Getting, M.D., Belmont
2nd Vice-President, Edwin H. Place, M.D., Bethesda, Md.
Secretary, May C. Welch, Malden
Treasurer, Catharine Atwood, Boston

Representative to Governing Council of A.P.H.A., L. Jackson Smith, M.D., Springfield

FEDERAL BILLS PROPOSE CONTINUING SOCIAL PROTECTION DIVISION

The American Social Hygiene Association, New York City, is sponsoring the continuation in peace time of the federal services to the states provided since early in 1941 by the Federal Security Agency's Social Protection Division. Two bills have been introduced into Congress (H.R. 5234 by Representative Bolton and S. 1779 introduced by Senators Pepper, George, LaFollette and Taft). In connection with its promotion of these bills, the A.S.H.A. has published an analysis of a series of 2,276 studies in more than 1,100 communities near which members of the armed forces are stationed. This report is republished with permission of the A.S.H.A.

PROGRESS IN THE REPRESSION OF COMMERCIALIZED PROSTITUTION

An analysis of a series of 2,276 studies made by the American Social Hygiene Association, January 1, 1940—December 31, 1945, in 1,170 communities near which members of the armed forces are stationed

NOTE: In arriving at an opinion as to whether conditions in a given community should be classified as "good," "fair," "poor" or "bad," a number of closely related factors had to be taken into consideration. Briefly these are: (1) size of the community; (2) actual amount of prostitution activity found at time of survey; (3) accessibility of prostitutes, whether hard or easy to find. These factors are considered together to provide the basis for classification.

NATIONAL INSTITUTE OF HYDROLOGIC
AND CLIMATIC MEDICINE

IN HAVANA

The inauguration on the grounds of the Finlay Institute of the National Institute of Hydrologic and Climatic Medicine was announced by Dr. Luis Espinosa y G. Caceres, of the Ministerio de Salubridad y Asistencia Social, Cuba. Dr. Victor Santamarina is in charge.

COLONEL THOMAS B. TURNER AWARDED
LEGION OF MERIT

Colonel Thomas B. Turner, former Director of the Civil Public Health Division, Office of The Surgeon General, has received the Legion of Merit for his part in "some of the most important advances made in Preventive Medicine Service during World War II.

Commissioned into the Army Medical Corps as a Lieutenant Colonel in January, 1942, Colonel Turner was appointed Director of the Venereal Disease Control Division in the Office of The Surgeon General. In January, 1944, he was designated Director of the Civil Public Health Division, where he served until his separation from service in January.

Prior to his entrance into the Army, Col. Turner was Professor of Bacteriology and in charge of the Division of Venereal Disease in the Johns Hopkins University School of Hygiene and Public Health, and served as consultant in venereal disease to the Rockefeller Foundation.

COLONEL E. R. LONG AWARDED
LEGION OF MERIT

Colonel E. R. Long, MC, Chief Consultant in Tuberculosis, Office of The Surgeon General, has been awarded the Legion of Merit for his work in the "initiation and development of standards and measures for the detection of tuberculosis."

Colonel Long's distinguished service in also establishing "priceless permanent

files of chest x-ray films of Army personnel," together with his methods of tuberculosis detection, was "of outstanding and lasting significance to the public health program of the country," according to the citation.

Commissioned into the Army as a Lieutenant Colonel in July, 1942, Colonel Long acted as Chief of the Tuberculosis Section, Medicine Branch, Medical Practice Division of The Surgeon General's Office. From July, 1943, until December, 1943, he was Chief of the Medicine Branch and had been promoted to Colonel. In January, 1944, he became Assistant Chief of the Professional Service and in August of the same year was assigned to his present position as Deputy Chief of the Professional Administrative Service. He was appointed Consultant in Tuberculosis in January, 1944.

During the past year he was visiting Consultant in Tuberculosis in the Mediterranean and European Theaters of Operation; Chief of the Tuberculosis Section of the Public Health Branch, Office of the Military Government, U. S. Zone, Germany; and Acting Director of the Tuberculosis Service, Veterans Administration.

Prior to entering the Army, he was Director of the Henry Phipps Institute and Professor of Pathology at the University of Pennsylvania.

STUDY CITY-COUNTY CONSOLIDATION

In Jefferson County, Alabama, which includes the City of Birmingham, a commission to study the question of city-county consolidation was organized late in 1945 under the authority of the 1945 legislature. The president of Howard University was elected chairman and the director of the Bureau of Public Administration at the University of Alabama, secretary. This commission is charged by law to report its findings to the 1947 session of the legislature. Some three years ago the Bureau of Pub-

lic Administration, at the request of the Jefferson County legislative delegation, made a survey of the feasibility of consolidating the county and city school systems.

DR. LEONARD A. SCHEELE RECEIVES U. S.
TYPHUS MEDAL

The War Department, Washington, D. C., has announced that Dr. Leonard A. Scheele, Senior Surgeon, U. S. Public Health Service, has been awarded the United States of America Typhus Commission Medal for "exceptionally meritorious service in connection with the work of the Typhus Commission during the period 1944-1945 in the European Theater of Operations. As Chief of Preventive Medicine Section, Public Health Branch, G-5, Supreme Headquarters, Allied Expeditionary Forces, Dr. Scheele took an important part in the development of policies, the determination of plans, and the accumulation of supplies essential for typhus control among refugees and displaced persons in zones of Northwest Europe regained from the Germans by British and American forces. Through his personal qualities he inspired coöperation and coördination between agencies, international as well as American, civilian as well as military, and groups concerned with typhus control in these regions. His contributions aided directly in preventing the spread of typhus in Northwest Europe."

Dr. Scheele has returned to the National Institute of Health and is serving as Assistant Chief of the National Cancer Institute, Bethesda, Md.

U. S. ARMY ANNOUNCES NEW ANTI-
MALARIAL DRUG

The Surgeon General of the U. S. Army announced in February that the new anti-malarial drug, SN-7618, which the Army Medical Department played an important part in developing, has been found to be superior in many ways

to quinine or atabrine. Studied in collaboration with the Interservice Board for the Coördination of Malarial Studies, SN-7618 was tested in experiments at Harmon General Hospital, Longview, Tex., and Moore General Hospital at Swannanoa, N. C., in addition to some overseas theaters of operations.

Designed to obtain information on the value of the drug in controlling the symptoms and fever occurring in acute attacks of malaria, these studies included the observation of more than 600 malaria-stricken soldiers, who were given different amounts of the drug in from one to seven days. When notations had been made of symptoms such as the passing of the fever and the disappearance of malarial parasites from the blood stream, the patients were kept in the reconditioning section to determine the possibilities and time intervals for relapse. Comparisons were made of the results with those obtained in similar studies of atabrine, quinine, and other new drugs. It was found that one day's treatment with SN-7618 promptly controlled fever and other symptoms, and that the parasites rapidly disappeared from the blood.

Observation periods of four months showed that 75 per cent of the men tested suffered relapses. Though this number is similar to that found in experiments with quinine and atabrine, the interval between attacks was found to be longer when SN-7618 was used. Patients soon acquired a preference for the drug because of its rapid action, which permitted them to leave the wards within two or three days. Though SN-7618 is considered superior to other anti-malarial drugs in that it does not discolor the skin, upset the stomach, or cause a buzzing in the ears, it is not a one-treatment cure for vivax malaria. Weekly doses of the drug can be taken to avoid relapse after an acute attack, but upon discontinuation of the treatment further relapses may occur.

SN-7618 was so named because it was the 7618th drug tested in the four year program sponsored by the Committee on Medical Research. The program was financed by the Office of Scientific Research and Development.

CHANNELS FOR OVERSEAS FOOD RELIEF

Inquiries which have reached the office of the American Public Health Association as to approved channels for providing food for overseas relief have prompted inquiries on behalf of those who are desirous of adding private subscriptions to the public effort.

The Victory Collection of Canned Food, conducted by the Community Canning Program for Overseas Relief and on behalf of the United Nations Relief and Rehabilitation Administration, has offices at 100 Maiden Lane, New York 7, N. Y. This agency through UNRRA channels is prepared to expedite the distribution of foods throughout Europe, Asia, and the Philippines and wherever UNRRA channels are in operation. According to the statement by this organization, there are more than twenty-eight million persons in Europe alone who will get less than 1,500 calories per day and large groups who will receive as little as 1,000 calories, or one-half enough for subsistence. Contributed canned food will be distributed free overseas and funds for the purchase of food may be sent to the Victory Food Collection at the above address.

NEW YORK ACADEMY OF MEDICINE INSISTS ON STANDARDS FOR COMMISSIONER

Resolution adopted at a meeting of the Committee on Public Health Relations of The New York Academy of Medicine, March 11, 1946

RESOLVED, That with the approval of the President of the Academy the following statement be sent to the Mayor of the City of New York.

Upon the recommendation of its

Committee on Public Health Relations which has given this matter serious consideration, The New York Academy of Medicine desires to call the attention of Mayor O'Dwyer to the fact that his recent appointment of a successor to Dr. Ernest L. Stebbins is contrary to paragraph 551b of Chapter 22 of the Charter of the City of New York which requires that the Commissioner of Health shall have had at least 8 years' experience either in public health administration or teaching or both. These mandatory qualifications of the City Charter are comparable to the training and experience required by the State of New York for health officers of all other cities in the State with a population of more than 50,000.

In pointing out that Dr. Edward M. Bernecker has not had the training or experience in public health administration or teaching required by the Charter, and therefore does not qualify under the Law for the position of Health Commissioner of the City of New York, the Academy has no intention of questioning his personal integrity or his qualifications as a hospital administrator. It wishes rather to indicate to the Mayor that experience in hospital administration is in no way equivalent to that training or experience in modern public health practice which a Health Commissioner requires in arriving at important decisions daily which may affect the health of almost eight million people. The appointment of a person not meeting the Charter qualifications as Health Commissioner of the City of New York constitutes a reversion to the public health standards of a past generation, before public health administration had developed into a complicated and highly skilled specialty, and before outstanding schools of Public Health had been established at the major universities of this country.

In the opinion of the Academy, the people of the City of New York de-

serve the services as Health Commissioner of the best qualified person available in this country. It was with this objective that the State of New York secured the services of its last Commissioner, Dr. Thomas Parran, who subsequently rose to be the Surgeon General of the United States Public Health Service, and that the City of New York secured the services of Dr. Ernest L. Stebbins who now leaves the employ of the City after a period of distinguished service, to become Professor of Public Health Administration and head of the great School of Public Health at the Johns Hopkins University.

The Academy, therefore, urges the Mayor to rescind his recent action, and to appoint as Commissioner of Health one who possesses the training and experience required by the City Charter and who will maintain and extend high standards of public health in this City, and, by example, throughout the Nation.

RHEUMATIC FEVER FOUNDATION IN SYRACUSE

The Rheumatic Fever Foundation of Onondaga County, New York, was incorporated on October 26, 1945. As its first activity, a 40 bed composite medical center, home, school, and church for the care and treatment of children suffering from rheumatic fever and rheumatic heart disease was opened in Syracuse. The objectives of the Foundation are to maintain a hospital and dispensary for treatment, a coordinated clinic for the follow-up of discharged patients, to maintain a research laboratory, and to cooperate with other

agencies in the prevention, detection, and treatment of rheumatic fever and its complications. It has a seven-man board made up of two physicians and five laymen.

PERSONALS

Central States

FRANCIS E. COLIEN, PH.D.,* has been honorably discharged from the Sanitary Corps with the rank of Lieutenant Colonel, having served as executive officer and chief of the Laboratory Service in Sanitary Corps assignments. He returns to his former position as associate professor of bacteriology and public health and preventive medicine at Creighton University School of Medicine, Omaha, and as director of the Omaha Department of Health Laboratories.

JOHN M. HEPLER, C.E.,* Director of the Bureau of Engineering, Michigan Department of Health, Lansing, recently spent several weeks in Puerto Rico at the School of Tropical Medicine, San Juan, lecturing on public health engineering and attending the meetings of the Puerto Rico Public Health Association.

LEWIS S. JORDAN, M.D., Granite Falls, Minn., was elected President of the Minnesota Public Health Association recently to succeed FRANCIS E. HARRINGTON, M.D.,† Minneapolis.

WALTER B. QUISENBERRY, M.D.,* who recently completed a course at the Johns Hopkins School of Hygiene and Public Health, Baltimore, has been appointed Director of the State Division of Venereal Disease Control in Nebraska, succeeding REGINALD A. FRARY, M.D.,† resigned.

MARY E. W. SOULES, M.D.,† of Dickinson, No. Dak., was recently appointed Director of the Southwest District Health Unit which comprises the counties of Slope, Bow-

man, Golden Valley, Billings, Hettiger and Adams.

LT. COL. JOHN T. TRIPP,* Director of the Division of Biologic Products in the Michigan State Department of Health laboratories, Lansing, has returned from China where he spent 18 months under the Department of State Cultural Cooperation Program. Col. Tripp helped to set up a central laboratory in China for the standardization of biological products.

ROBERT YOHO,† who has been connected with the Indiana State Board of Health, has been appointed Director of the Division of Health and Physical Education.

Eastern States

BAILEY B. BURRITT † was elected President of the New York Tuberculosis and Health Association at the annual meeting of the Society in January.

SUE THOMPSON GOULD, M.D., M.S. P.H.,* who has been Acting Commissioner of the Columbia County Department of Health, Hudson, N. Y., since 1942 has been named Commissioner for a six year term.

MORRIS B. JACOBS, PH.D.,† Senior Chemist in the New York City Department of Health, has been appointed chief of the Chemical Laboratory of the Department.

MORTON A. SEIDENFELD, PH.D.,† recently Lieutenant Colonel in the Division of Neuropsychiatry of the Surgeon General's Office, U. S. Army, has been appointed Director of Psychological Services for the National Foundation for Infantile Paralysis, New York City.

HARRY P. WAREHAM, Rochester, N. Y., has been appointed Executive Vice President of the American Society for the Hard of Hearing, Washington, D. C., effective March 1. Since 1919,

Mr. Wareham has been identified with Community Chest activities in Rochester and other cities.

The appointment of ISRAEL WEINSTEIN, M.D.,* of New York City as Deputy Commissioner of Health, New York City Department of Health, succeeding FRANK A. CALDERONE, M.D., M.P.H.,* was announced on March 6. Dr. Weinstein formerly was director of the Bureau of Health Education in New York City and more recently has served with the armed forces.

JOHN S. WHEELER, M.D.,† released December 1 from the Army with the rank of Major, has been appointed State Health Officer of New Hampshire, succeeding ALFRED L. FRECHETTE, M.D.,† Concord. MARY M. ATCHINSON, M.D.,† Acting Deputy Health Officer in the Department, has been appointed Deputy Health Officer.

CHARLES A. ZELLER, M.D., Superintendent of the Philadelphia State Hospital, has accepted the appointment as Director of the Michigan Department of Mental Health, effective March 1.

Southern States

CHANGES IN HEALTH PERSONNEL IN FLORIDA:

E. J. TEAGARDEN, M.D., has resigned as Director of the Division of Tuberculosis Control of the State Board of Health, effective December 31, 1945. DR. CLARKE W. MANGUN,† now Assistant, will serve as Acting Director temporarily.

J. O. BARFIELD, M.D.,† who has served for the past 5 years as Director of the Bay County Health Dept. with headquarters at Panama City, resigned December 15, 1945, to enter Government service.

ROBERT FAWCETT SAYRE, M.D., has been released from service in the

* Fellow A.P.H.A.
† Member, A.P.H.A.

Army Medical Corps and appointed Director of the Northern Florida Health District, with headquarters at Lake City, effective December 15, 1945.

JAY C. MILLER, M.D.,† of the U. S. Public Health Service, who has been Acting Director of the Bradford-Clay-Union Health Unit was transferred by the Public Health Service to a station in another State, effective January 3.

LORENZO L. PARKS, M.D.,† recently returned from foreign service, has been appointed Director of the Duval County Health Department with headquarters at Jacksonville. Dr. Parks, previous to his military service, was Director of the Bureau of Local Health Service.

CHANGES IN HEALTH PERSONNEL IN KENTUCKY:

GEORGE M. WELLS, M.D., Bowling Green, has returned to the Directorship of the Warren and Simpson County Health Departments, succeeding PAUL Q. PETERSON, M.D.,† who has been granted a scholarship in public health at the University of Michigan.

RAYMOND E. WEHR, M.D., Newport, has been named Health Officer of Campbell County.

FRANK K. SEWELL, M.D.,† has been named Health Officer for the Knox, Whitley and Laurel County Health District, succeeding RICHARD B. FULKS, M.D.,† Barbourville, who has been granted a fellowship to pursue a course in public health.

JOE W. SAVAGE of Charleston, W. Va., has been appointed Executive Director of the National Foundation for Infantile Paralysis, New York City. Mr. Savage, who recently was a major in the Army Air Corps, was for more

than 12 years Executive Secretary of the West Virginia Medical Association.

Western States

ISABEL M. GONZALES has been appointed to the position of Spanish Health Education Worker in the Denver Tuberculosis Society, Denver, Colo. She will organize the Spanish-speaking population in health activities.

LELAND E. POWERS, M.D.,† formerly of Seattle, Wash., who for the last year has served as chief medical officer of UNRRA in China, returned to the State of Washington in February to assume a connection at the University of Washington. Dr. Powers was formerly Washington State Health Officer.

CHANGES IN HEALTH PERSONNEL IN WASHINGTON STATE:

LEONARD A. DEWEY, M.D., upon his discharge from the Armed Services, returned to his work as Head of the Venereal Disease Control Section on February 1. DR. GEIDT, Head of the Epidemiology Section, took charge of Dr. Dewey's Section while he was away.

ROY M. HARRIS, who has been on Military Leave, returned to his former position as Chief of the Division of Public Health Engineering on February 8. EMIL C. JENSEN, who has been Acting Chief of this Division, has returned to his former position as Head of the Sanitary Engineering Section.

RALPH R. SACHS, M.D.,† was appointed Head of the Field Consultation Section in the Washington State Department of Health's Division of Local Health Services, on January 14. Dr. Sachs was formerly Public Health Supervisor for the Hanford Engineer Works, Washington's atomic bomb project.

* Fellow A.P.H.A.

† Member, A.P.H.A.

RALPH L. NIELSON was recently appointed Director of the survey of hospital and health center facilities throughout the state and to formulate a plan for the coordinated development of hospital facilities. Mr. Nielsen was formerly Assistant Agriculture Economist for the Southwest Region of the U. S. Department of Agriculture and was stationed at Berkeley, Calif.

Foreign

LT. COL. ROBERT C. HUME, M.D.,† now on terminal leave after his return from overseas duty as Public Health Officer for U. S. Military Government in Vienna, has joined the Medical Department of Standard Oil Company of New Jersey, with offices in New York City.

CAPT. THEODORE R. MEYER, MC, USNR,* has returned from Greece after 10 months' duty as Officer in Charge of a special Navy epidemiological unit formed at the request of the Greek Government for the purpose of improving public health conditions in that country. Capt. Meyer is now on temporary duty in the Bureau of Medicine and Surgery, Navy Department. He was Health Commissioner of St. Louis County prior to his entry into active duty in the Navy in 1941.

FLORINE THOMASON, R.N., formerly Assistant Director of Nursing Service of the Eastern Area of the American Red Cross, has returned from 3 years of overseas duty with the Army Nurse Corps and is now Associate Director of the Volunteer Nurse's Aide Corps, with her office at Red Cross national headquarters, Washington, D. C.

Deaths

The death of MRS. JESSE W. LAZEAR, widow of the Late DR. JESSE W.

LAZEAR of the U. S. Public Health Service, who died during his investigation of yellow fever in 1900, was announced in Santa Barbara, Calif., on February 26.

MAJOR WILLIAM HENRY LLOYD,† U. S. Army Medical Corps, Retired, died on February 14 at his home in Mt. Victoria, Md., of coronary thrombosis. He was in his 69th year.

RESUMPTION OF CONFERENCE CALENDAR WITH THE APRIL JOURNAL

The Calendar of Conferences and Dates which the *Journal* carried until the ban on conventions by the Office of Defense Transportation last year, was useful to many persons. Now that conventions are being held again, it is being resumed with this issue. The Editors will welcome information about future meetings of state, regional, or national interest.

LUMETRON

Photoelectric Colorimeter Mod. 450 for Nessler Tubes

A new photoelectric instrument of high accuracy for the measurement of color and turbidity as well as for all analytical colorimetric tests in the sanitary examination of potable and purified water.

- Turbidity tests in terms of APHA (ppm) scale.
- Color tests in terms of APHA (mg pt) scale.
- Suited for determination of ammonia nitrogen, nitrate, nitrite, and for all other colorimetric tests according to APHA "Standard Methods".
- Operates with all "low-form" Nessler tubes 32 mm O.D., 200 mm high. Requires no matched sets of tubes.

LUMETRON Mod. 450 eliminates the uncertainties of visual matching methods. It requires no permanent color standards and furnishes reproducible results independent of individual judgment and of light conditions.

Acute Respiratory Disease Among New Recruits^{*†}

Commission on Acute Respiratory Diseases ‡

IT has long been recognized in the armed forces that new recruits experience an unusually high incidence of hospital admissions for respiratory diseases in contrast to seasoned men.¹ Although numerous factors have been considered to be important in causing this phenomenon, there has been a paucity of quantitative data by which these factors could be evaluated.

Studies of the Commission on Acute Respiratory Diseases at Fort Bragg, North Carolina, during the winter of

1942-1943² revealed that sharply defined epidemics of undifferentiated respiratory disease occurred with great regularity among newly inducted soldiers. Similar epidemics were not observed among seasoned men. These studies have now been extended to include observations over a period of two and one-half years. The incidence of respiratory diseases, as measured by hospitalized cases, has conformed to a characteristic epidemiological pattern, which helps to define the problem. In the present paper, the salient features of this pattern will be described and its implications regarding the nature of these diseases and the factors which influence their occurrence will be discussed.

SOURCE OF DATA

The studies began in October, 1942, and have continued through 1945. Consistently throughout this period acute undifferentiated respiratory disease of unknown etiology has comprised the great majority of the hospitalized cases of respiratory disease, except during an epidemic of influenza A in December, 1943. Primary atypical pneumonia has been continuously pres-

* From the Respiratory Diseases Commission Laboratory, Regional Station Hospital, Section 2, Fort Bragg, North Carolina.

† This investigation was supported through the Commission on Acute Respiratory Diseases, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, Preventive Medicine Service, Office of the Surgeon General, United States Army, and by grants from the Commonwealth Fund, the W. K. Kellogg Foundation, the John and Mary R. Markle Foundation, and the International Health Division of the Rockefeller Foundation to the Board for the Investigation and Control of Influenza and Other Epidemic Diseases for the Commission on Acute Respiratory Diseases.

‡ Members and professional associates of the Commission on Acute Respiratory Diseases are: John H. Dingle, Major MC, AUS, Director; Theodore J. Abernethy, Major, MC, AUS; George F. Badger, Major, MC, AUS; Joseph W. Beard, M.D.; Norman L. Cressy, Major, MC, AUS; A. E. Feller, M.D.; Irving Gordon, M.D.; Alexander D. Langmuir, Major, MC, AUS; Charles H. Rammelkamp, Jr., M.D.; Elias Strauss, Captain, MC, AUS; and Hugh Tatlock, Captain, MC, AUS.

ent in moderate incidence amounting roughly to 10 per cent of the respiratory admissions. These cases have been widely distributed throughout the post. Acute bacterial infections, such as hemolytic streptococcal pharyngitis and pneumococcal pneumonia have been sporadic and infrequent.³⁻⁶ At no time have they contributed significantly to the level of the incidence rates for total respiratory disease.

The data reported in this paper have been obtained largely by tabulating the daily admissions to the respiratory wards, without attempting to separate these cases into diagnostic groups. Thus the figures are based on the initial impression at the time of admission that the patients were suffering from some form of respiratory disease. Repeated checks of this rather rough method of measuring incidence have revealed a 90 per cent or greater accuracy, when compared with the final diagnoses made at the time of disposition. Because diseases of known etiology have been infrequent, this method of counting total respiratory admissions provides a reasonably accurate measure of the incidence of acute undifferentiated respiratory disease. For convenience this group of illnesses of unknown etiology will be referred to by the contraction "ARD."

In addition to the data based on total respiratory admissions, certain other studies will be reported which serve to emphasize the main points derived from the broad scale data. These studies have been based either on final diagnoses of hospital cases, or on the results of detailed clinical, epidemiological, and laboratory investigations of selected organizations.

The organization in which most of the studies of new recruits have been made is the Field Artillery Replacement Training Center (FA-RTC). The trainees enter the FA-RTC directly from reception centers in all parts of the

United States. With few exceptions the men have had less than one month of military experience prior to their arrival, and the majority have been in the army less than 10 days. Most of the men arrive in groups of 1,000 and form a battalion which is divided into batteries of 250 men. A varying number of battalions, from 5 to more than 12, have been under observation.

The courses of basic training have varied. In 1942 and early in 1943 they were 6, 8, or 13 weeks in duration. Since the late summer of 1943, however, all courses of training have lasted for 17 weeks. Upon completion of training, the men are transferred to other stations and a new group of trainees is brought in. Thus, throughout the period of study there has been a staggered flow of large groups of trainees through the FA-RTC. This movement of troops provides a basis for continuing epidemiological studies which in many ways resemble the techniques which have been used in experimental epidemiological studies in animal colonies.

The other organizations at Fort Bragg comprise a wide variety of tactical and service units which are composed largely of well seasoned men.* Many of these units have been under observation for 6 months or longer. Some of them have received small complements of new recruits from time to time. This was particularly true during the winter of 1942-1943.

INCIDENCE OF ACUTE RESPIRATORY DISEASE IN NEW RECRUITS AND SEASONED MEN

The weekly incidence rates of respiratory admissions in the FA-RTC and

* A large majority of the seasoned men were members of combat Divisions and Field Artillery Battalions who were undergoing active field training similar to or more intensive than that being given to the new recruits in the FA-RTC. Only a small proportion of the men included among "other organizations" were service troops of the Station Complement.

RESPIRATORY ADMISSION RATES - FORT BRAGG, N. C.
FA-RTC AND OTHER ORGANIZATIONS - 31 OCTOBER 42 TO 30 MARCH 45

FIGURE 1—Respiratory Admission Rates, Fort Bragg, N. C., FA-RTC, and Other Organizations, October 31, 1942, to March 30, 1945

from the other organizations stationed at Fort Bragg are shown in Figure 1, from October, 1942, to March, 1945. Throughout this entire period the new recruits in the FA-RTC have experienced a consistently higher incidence of ARD than the seasoned men. During the summer the difference has been small, approximating a ratio of 2 to 1 or less. In the winter, the ratio has been as great as 10 to 1, or more. A sharp rise in respiratory admissions has occurred in December or early January, reached a peak, and then rapidly subsided in the course of 5 to 6 weeks. During this period recruits, in various stages of training, have been affected. Subsequent to this first wave secondary waves have appeared each year. These secondary waves have been determined solely by the rate of arrival of new trainees. In February and March, 1943, the secondary wave was severe because a large number of new recruits entered the FA-RTC at this time. In

1944 and 1945 the secondary peaks were lower because the movement of new recruits was proportionately reduced, due to the lengthening of the training period.

In the other organizations, composed largely of seasoned men, the incidence of admissions has remained constantly low with only 2 exceptions. Moderate increases were observed in the winter of 1942-1943. These were the result, in large part, of the addition of complements of new recruits to organizations of seasoned men. During December, 1943, the influenza A epidemic affected both new recruits and seasoned men in approximately equal severity, but with the subsidence of this epidemic the rates among the units of seasoned troops fell to a low level and remained low throughout the rest of the winter.

In the winter of 1944-1945 an increase among seasoned men was barely perceptible. No epidemics of specific infections were recognized and prac-

tically no complements of seasoned men were added to these tactical organizations during this winter.

This difference in incidence of respiratory admissions between the FA-RTC and the other organizations may be due in part to varying criteria for admission to the hospital. In the FA-RTC the principal criterion has been the presence of a fever of 100 degrees or more, while in some, but not all, of the other organizations, a somewhat higher fever has been the indication for hospitalization. This difference might possibly account for the 2 to 1 ratio observed in the FA-RTC during the summertime; but it does not explain the 10 to 1 difference during the winter because during the epidemic of influenza A the incidence of admissions among the two types of soldiers was approximately equal. Furthermore, varying criteria

of admission do not explain the high incidence observed among the complements of new recruits which have been added to seasoned organizations, because under these conditions both new recruits and seasoned men received medical care in the same dispensaries.

The curve of respiratory admission rates in the FA-RTC represents a composite of the experience of many battalions. Each battalion of new recruits has followed a characteristic pattern which varies with the season. During the winter a battalion of newly arrived recruits experiences a sharply defined epidemic of 3 to 4 weeks' duration. A typical example is shown in Figure 2. During the first week after arrival, the rates are usually moderately elevated. They increase sharply to a peak in the second or third week, and then rapidly subside, following which the rates re-

FIGURE 2—Respiratory Admission Rates per 1,000 per Week, Among Batteries of a Battalion of New Recruits, FA-RTC, December 12, 1942, to February 5, 1943

1942-1943

FIGURE 3—Respiratory Admission Rates per 1,000 per Week. Three Representative Battalions, FA-RTC, October 17, 1942, to July 2, 1943

main consistently low. From 15 to 30 per cent of the total strength may be admitted to the hospital within the first 4 weeks.

The consistency with which these epidemics occurred during the winter of 1942-1943 is shown in Figure 3. There was a striking similarity in the epidemics in each battalion of new recruits which arrived between the middle of December and the middle of April. During the spring months the epidemics declined in severity, and during the summer they were absent or barely discernible.

Battalions which begin training during the late summer and fall do not experience such epidemics until December or January, after they have completed from 1 to 3 months of training.

The epidemics which occur at this time are more irregular and less sharply defined, but the total admission rates are comparable with those of battalions which arrive during the winter. This phenomenon is shown in two of the battalions in Figure 3. It is brought out more clearly in the experience of subsequent years.

During the fall and winter of 1943-1944 two waves of respiratory diseases occurred among new recruits. These two waves are most clearly indicated in the battalions which were under continuous observation from October to February (Figure 4). During this period serological studies were performed on approximately 800 respiratory admissions. The first wave began on November 28 and extended through

FIGURE 4—Respiratory Admission Rates per 1,000 per Week, Three Representative Battalions, FA-RTC, October 9, 1943, to June 23, 1944

December 24. From 80 to 90 per cent of all respiratory admissions during this wave showed significant increases in antibody titer to influenza A.

The second wave began late in December and extended through January. Less than 5 per cent of the respiratory admissions during the second wave showed evidence of influenza A by serological tests. The first epidemic, therefore, was due almost solely to influenza A and the second was an epidemic of ARD. Of special interest was "F" battalion (Figure 4), which was filled with new recruits during the middle of December as the influenza epidemic was subsiding. A severe epidemic occurred in this group immediately following its arrival. Serological studies of the respiratory admissions revealed that less than 10 per cent of the cases were influenza A. These few cases were concentrated in the first and second week of training. Thus the epidemic was not

influenza A, but rather 90 per cent of the cases were ARD. Presumably these new recruits had already had their experience with influenza virus A prior to their arrival.

The battalions which were formed from new recruits arriving in February and March experienced moderate epidemics of ARD similar to, though somewhat less severe, than those observed in late winter and spring of the previous year. The incidence pattern of ARD during the winter season of 1943-1944 was essentially similar to that observed in the previous year, when the superimposed epidemic of influenza A is taken into account. The longer period of training which the recruits were undergoing during this period revealed more clearly than was possible in the previous year that epidemics of ARD among men who arrived in October may not occur until January, after they have completed 3 months of basic training.

FIGURE 5—Respiratory Admission Rates per 1,000 per Week, Three Representative Battalions, FA-RTC, September 23, 1944, to March 23, 1945

In 1944-1945 the respiratory season began during the first week of January (Figure 5). Definite epidemics appeared in each battalion, approximately simultaneously, although there were marked differences in the period during which the battalions had been training. Throughout this respiratory season an extensive search was conducted for cases of influenza A and B, hemolytic streptococcal infection, and other specific diseases. Only sporadic cases were found. Over 90 per cent of the respiratory admissions were classified as respiratory diseases of unknown etiology.⁵ Again the incidence pattern of ARD was similar to that observed in two previous years.

COMPARISON OF ARD WITH OTHER RESPIRATORY DISEASES

The characteristic differences in the epidemiology of ARD from other respiratory diseases may be emphasized by a comparison with three specific diseases which have been observed in epi-

demic form at Fort Bragg. These three diseases are influenza A, localized acute streptococcal pharyngitis, and German measles. During the fall and winter of 1943-1944 the respiratory admissions from "E" battalion were studied in detail⁶ (see Figure 4). By means of serological and bacteriological tests it was possible to separate more than 90 per cent of the cases into three diagnostic groups, influenza A, streptococcus pharyngitis, and ARD. The weekly incidence of these diseases is presented in Figure 6.

The wave of influenza swept through this battalion in early December and rapidly subsided. The wave of ARD in January was equally distinct and almost twice as severe as the epidemic of influenza. In November and early December two sporadic cases of beta-hemolytic streptococcal pharyngitis occurred and in the last weeks of December a small outbreak of 10 cases developed. All of these 12 cases were caused by a specific strain of group A

FIGURE 6—Weekly Incidence Rates of ARD, Influenza A, and Type 12 Streptococcus Pharyngitis in "E" Battalion, October 9, 1943, to February 11, 1944

hemolytic streptococcus, type 12. They were confined to four adjoining barracks. No other cases of streptococcal infection of any type were discovered in the remaining 12 barracks of the battalion during the 4 months of this study.

An epidemic of German measles occurred during the late winter and early spring of 1943.² Large numbers of cases appeared, not only in the FA-RTC but also among many organizations of seasoned men. During this period 9 separate groups of new recruits were under observation. In 7 of these 9 groups, the peak incidence of German measles occurred during the week ending March 26. In one group, an equal number of cases occurred during the weeks ending March 19 and March 26 and in only 1 group did the highest incidence of this disease occur earlier.

In Figure 7, the time of occurrence of German measles is contrasted to that of epidemic ARD in 5 representative battalions. The cases were clearly concentrated during the month of March.

This concentration appeared to be unrelated to the time of arrival of the recruits.

These 3 specific diseases, influenza A, German measles, and type 12 streptococcus pharyngitis all showed epidemiological features which were distinct and characteristic. The first 2 infections occurred in both seasoned men and new recruits. The third was sharply localized to a few barracks. During a 3 year period epidemics of influenza A and German measles have been observed only once, although scattered cases of these two infections were seen, both before and subsequent to these epidemics. No widespread epidemics of streptococcal infection have been observed in the FA-RTC and only a few localized epidemics, such as the one described, have been detected, although sporadic cases have been present in small numbers.

The epidemic waves of ARD in December and January bear some resemblance to the waves of influenza A and

FIGURE 7—Incidence of Admissions for Respiratory Disease and German Measles in 5 Representative Battalions, FA-RTC, January 23 to April 30, 1943

*Reprinted from American Journal of Public Health*²

German measles in that they affect all organizations of new recruits in various stages of training. They are different, however, in that they do not affect seasoned men. Furthermore, they recur each year. Each group of new recruits which arrives, subsequent to the first wave, also is affected.

DISCUSSION

Acute undifferentiated respiratory disease (ARD) at Fort Bragg has shown characteristic epidemiological features over a period of three consecutive respiratory seasons. The pattern has recurred in a consistent manner each year and it has been distinct from that of certain diseases of known cause. These findings suggest that ARD is a specific disease process due to a single

or to a group of closely related agents.⁷

The sharply defined epidemics which occur during winter months among new recruits indicate that these men are highly susceptible to the disease. The rapid subsidence of the epidemics implies some form of an immunity mechanism. From the consistently low incidence following the epidemics it may be inferred that this immunity is maintained for several months. Absence of epidemics of ARD in seasoned troops at Fort Bragg suggests that the immunity lasts for a considerable period, possibly 1 to 2 years or longer.

Certain factors have been considered to be important in causing respiratory disease among soldiers. Among these are: (1) the exchange of nasopharyngeal flora among men who are brought to-

gether from different geographic regions; (2) exhaustion from the arduous physical training program; (3) reactions to the immunization procedures; and, (4) difficulties in psychological adjustment to military life.

The findings at Fort Bragg do not support any of these factors as having primary importance. The epidemics which occur at the beginning of the respiratory season among recruits who have been in training for several months cannot be explained by these factors. By this time the men are well adjusted to army life, the immunization program is completed, they are hardened physically, and the opportunity to exchange flora has been present for several months.

Another factor which is commonly thought to be important in the causation of respiratory disease is exposure to inclement weather. During the training period each battalion undergoes field exercises during which the men sleep in the field in all types of weather. Epidemics of ARD have occurred prior to, during, and subsequent to these field bivouacs in approximately equal severity. Since the rigors of life in the field may be excessive in contrast to life in garrison it would appear that exposure to the elements is not of primary importance in causing epidemics of ARD.

Unsanitary mess halls and inadequately washed dishes also have been much discussed as potential sources of spread of respiratory diseases. It is difficult to explain the epidemics of ARD at Fort Bragg on this basis. The mess halls of the FA-RTC have been notable for their consistently excellent sanitary condition. It is doubtful that the sanitary standards in more than 60 mess halls break down simultaneously each winter, or that in the late winter and spring only those mess halls serving newly arrived recruits are in an unsanitary state.

Although these commonly held beliefs do not appear to have been primary factors in causing epidemics of ARD at Fort Bragg, it is entirely possible that some of them may have been secondary or contributing factors that influence the severity and extent of the disease.

One factor of unquestioned importance in the occurrence of ARD is the season of the year. Epidemics have occurred at Fort Bragg regularly during the winter and early spring but none have been observed during the summer and early fall. Similar seasonal variations are well recognized for most acute respiratory and contagious diseases in temperate climates. The mechanism of this seasonal effect is an obscure and probably complex problem.

A limited amount of evidence suggests that these epidemiological findings may be applicable to other Army posts and possibly to civilian life. An almost identical pattern has been observed in one large Naval Training Station in New England.^{8, 9} In many military installations which receive a constant flow of recruits rather than a staggered flow, such as that at Fort Bragg, the pattern is less apparent, but it has been shown that, during the winter months, new recruits are most susceptible to common respiratory diseases during the first 4 to 6 weeks of military life.¹⁰⁻¹³ In many of these studies the epidemiological pattern has been complex, due to the epidemic occurrence of influenza A or B, acute streptococcal infections, and pneumococcal pneumonia.^{11, 14-20}

Evidence that a similar pattern operates in civilian life is difficult to ascertain because of the great difference in the environment and living conditions. The waves of respiratory disease that are observed in schools²¹ and colleges²² may represent a modified form of the same phenomenon. It should be pointed out that these semi-isolated and semi-regimented civilian populations have some characteristics which are similar

to military organizations. It is questionable that the distinction between new recruits and seasoned men is generally applicable to civilian life. Much further study, under varying conditions, in different geographic regions, and over a period of years, will be necessary before the significance of the epidemiological pattern observed at Fort Bragg can be fully interpreted.

It should be reemphasized that the present observations are derived solely from a study of hospitalized cases of respiratory disease. Such cases represent only the severe form of illnesses which may be widespread among men who remain in the field. Furthermore, in addition to mild illnesses of the same specific nature as ARD, other types of respiratory illnesses which only rarely result in hospitalization may also be prevalent. Studies of dispensary cases, 1943-1944⁶ and 1944-1945⁵ showed that during the late summer and fall months the incidence of non-hospitalized cases of respiratory disease increased considerably without a corresponding rise in hospital admissions. Thus the incidence pattern of minor respiratory illnesses differs from that of hospitalized cases of ARD. This finding suggests that at least some of the minor illnesses may have resulted from a different specific cause.

It is impossible to determine whether the diseases which have been observed among new recruits at Fort Bragg correspond with the common forms of respiratory disease, such as the common cold, which are seen generally in civilian life. It is reasonable to suppose that they do, but the total lack of adequate means of differential diagnosis prevents the elucidation of this point.

These observations have been presented as deductions based primarily on epidemiological evidence. They are not considered as final conclusions but rather are presented in the hope that they may help to define some of the

problems in the study of acute respiratory disease of unknown etiology, and that they may aid in the interpretation of epidemiological and clinical investigations of specific respiratory diseases.

ACKNOWLEDGMENTS—The Commission on Acute Respiratory Diseases wishes to thank the following officers for their active support which made these studies possible:

Major General D. C. Cubbison
Brigadier General J. T. Kennedy
Brigadier General H. C. Coburn, Jr.
Colonel G. D. Chunn
Colonel J. N. Williams
Colonel R. J. Horr
Colonel W. B. Daniels
Lieutenant Colonel F. W. Bryant
Lieutenant Colonel J. M. Kinsman

and the commanding officers and their staffs of the regiments, battalions, and batteries of the FA-RTC.

The following men have rendered valuable assistance during the course of the studies:

Major G. R. Newton, Personnel Adjutant, FA-RTC
Major R. L. Siegel, Surgeon, FA-RTC
Major B. E. Moore, Surgeon, FA-RTC
Major W. J. McVey, Classification Officer, FA-RTC
Major A. M. Sands, Chief Sanitation Branch, FA-RTC
Captain D. Butterfield, Personnel Adjutant, FA-RTC
Captain L. M. Bowen, Registrar, Regional Hospital
Captain D. L. Martin, Registrar, Regional Hospital

and their staff officers and enlisted men. The medical officers on the wards, in the X-ray Service and in the Receiving Office have coöperated fully in this study.

Pasteurization of Liquid Egg Products

III. Destruction of Salmonella in Liquid Whole Egg^{*}

A. R. WINTER AND G. F. STEWART

Iowa Agricultural Experiment Station, Poultry Husbandry Subsection, Ames, Iowa

AND

VERNON H. McFARLANE AND M. SOLOWEY

United States Department of Agriculture, Bureau of Agricultural and Industrial Chemistry, Microbiology Research Division, Philadelphia, Pa.

THE presence of *Salmonella* organisms has been reported in hen, turkey, duck, goose, and pigeon eggs.¹⁻⁶ Less information is available in the literature concerning the occurrence of *Salmonella* in hens' egg products. Bornstein, *et al.*⁷ reported the isolation of *S. senftenberg* from a sample of Chinese egg powder. Gibbons and Moore⁸ isolated *S. bareilly*, *S. oranienburg*, *S. typhimurium*, *S. thompson*, *S. minnesota*, *S. pullorum*, *S. newport*, *S. manhattan*, and *S. potsdam* from samples of Canadian whole egg powder. Other isolations from egg powder have been reported.^{9, 10}

Pasteurization affords an effective means of destroying microorganisms in liquid egg.¹¹⁻¹⁴ It would seem to be the most logical method of destroying *Salmonella* in liquid egg, i.e., if possible to do so without affecting the desirable

properties of the treated product. In December, 1944, the U. S. Army Quartermaster Corps wrote into their tentative specifications for powdered whole egg the requirement that "The liquid egg just prior to drying shall be preheated by the flash method to not less than 140° F."

Neither pasteurization nor thermal death rate temperature and time relationships necessary to destroy *Salmonella* in liquid whole egg has been previously reported in the literature to the authors' knowledge. Some data are available, however, regarding the destruction of *Salmonella* in eggs, liquid egg, and egg mixes during cooking. It has been found¹ that soft boiling, codding, or frying on one side did not always render an egg free from *Salmonella* organisms. Eggs artificially infected with *S. pullorum*² required a 5 minute boiling period to kill all of the organisms. Van Oijen⁵ and Wedeman¹⁵ recommended that duck eggs be boiled 10 minutes before use or the broken out liquid be heated at 149° F. for 20 minutes to destroy *S. enteritidis* and *S. paratyphi*, which are sometimes

A report on a joint research project of the Quartermaster Corps (U. S. Army) Committee on Food Research, the Iowa Agricultural Experiment Station and the United States Department of Agriculture, Bureau of Agricultural and Industrial Chemistry.

^{*} *Journal Paper No. J-1339* of the Iowa Agricultural Experiment Station, Ames, Iowa, Project No. 755.

present. Merely bringing custard to a second boil, after the addition of a little thickening, was found to render it free from added *S. enteritidis*.¹⁶ Custard pies to which the organism had been added before baking were free from the organism when they left the oven. Gibbons and Moore¹⁷ used reconstituted egg powders, heavily contaminated with *S. bareilly*, *S. oranienburg*, and *S. typhimurium* in the preparation of scrambled eggs, omelets, sponge cakes, custards, and muffins. No *Salmonella* could be detected in the cooked foods. The scrambled eggs were prepared in 3 minutes and reached 179.6° F. The omelets were prepared in 4 to 5 minutes, and reached 201 to 208° F. A large custard was baked at 284° F. for 45 minutes. The muffins were baked 20 minutes at 410° F. The large sponge cakes were baked at 374° F. for 45 minutes.

The objective of the experiments described in this paper has been to determine pasteurization temperatures and times necessary to destroy different *Salmonella* types in liquid whole egg.

PROCEDURES

In the experiments which follow, batches of sterile or very low count *Salmonella*-free liquid whole egg were artificially inoculated with 40,000 to 1,000,000 *Salmonella* organisms per ml. Portions of each inoculated batch were then subjected to different pasteurization temperatures and times in an experimental pasteurizer, laboratory model.¹²

Twelve to 54 clean eggs with sound shells were used in the preparation of each batch of liquid. They were obtained from the Iowa State College *S. pullorum*-free flocks. The shell eggs were held a week at room temperature to make their age more comparable to eggs used in breaking plants. Preparatory to breaking, bacteria were removed from the shell surface by soaking

each egg in 1 per cent sodium hydroxide for 2 to 5 minutes, draining, dipping in 95 per cent alcohol and by flaming the adhering alcohol. Each egg was then broken separately into a sterile pint jar by cracking the shell on the edge and draining the contents into the jar. It was observed for appearance and odor. If normal, it was transferred to a sterile 2 quart jar. Any abnormal egg was discarded and the container replaced by a clean sterile one. The accumulated eggs in the larger jar were shaken to break the yolk membranes. The liquid egg was then passed through a hand homogenizer, strained through a double layer of cheesecloth, and poured into a sterile jar containing glass beads. After shaking the jar 100 times through a wide arc, a sample was removed for a plate count. The remaining liquid egg was then inoculated with a broth suspension of *Salmonella*. Melange and inoculum were quickly and violently shaken by hand 200 times. A sample was again removed for plating and then pasteurization operations were started immediately.

The inoculum for each of the *Salmonella* types was always prepared in the same manner. Different strains, 6 to 13, were grown in dextrose broth (Difco) at 37° C. One, 2, 3, and 4 day old cultures were made of each strain. Measured quantities of the broth cultures were combined to give a mixture of cells of different ages. Usually about 5 ml. of the well mixed composited broth suspension were used per 250 ml. of egg.

Uninoculated, inoculated (raw), and pasteurized samples were plated on tryptose glucose extract agar after the procedure outlined in the A.P.H.A. tentative methods for the microbiological examination of eggs and egg products.¹⁸ Plates were incubated at 37° C. (98.6° F.) for 72 hours. In event only one or two colonies of doubtful nature appeared on a plate, they were fished and transferred to Kligler's

iron agar (Difco) to which had been added 0.5 per cent sucrose, for determination of typical Salmonella reactions.

One hundred and sixty-four strains representing 16 Salmonella types isolated from egg powder were used in the pasteurization trials. Of these, 150 strains were isolated by the Microbiology Research Division (1943-1944) and were identified serologically by Dr. E. H. Spaulding, Temple University School of Medicine, Philadelphia, Pa. Fourteen strains consisting of one *S. montevideo*, four *S. oranienburg*, one *S. oregon*, three *S. tennessee*, and five *S. pullorum* were obtained from the Army Service Forces Seventh Service Command Medical Laboratory, Fort Omaha, Nebr.

RESULTS

Typical findings obtained during representative pasteurization runs for the different Salmonella types are shown in Tables 1-5 and Chart 1. It was not difficult to destroy Salmonella by heat. Practical pasteurization temperature and time relationships resulted in total destruction.

Of the sixteen types studied (Table 5), *S. senftenberg* was most resistant to heat and *S. pullorum* least resistant (Chart 1). Four of the eleven strains of *S. senftenberg* did not produce a darkening of Kligler's iron agar. A mixture of these strains was more resistant to heat than a mixture of the other seven strains, which darkened the medium.

Salmonella types commonly found in egg, namely, *S. pullorum*, *S. oranienburg*, *S. montevideo*, *S. tennessee*, *S. anatum*, *S. bareilly*, *S. typhimurium*, *S. meleagridis*, and the others tested (Table 5) with the exceptions of *S. senftenberg* and *S. cerro*, were completely destroyed at the following temperatures and within the following times:

	Minutes
150° F.....	0.3
148° F.....	0.8
146° F.....	0.8
144° F.....	1.2
142° F.....	2.0
140° F.....	2.6
138° F.....	3.7

The temperatures and times required

to kill *S. senftenberg* are shown in Table 3 and for *S. cerro* in Table 4.

DISCUSSION

Data in Tables 1-5 not only show the comparative efficiencies of different temperature and time combinations in destroying Salmonella organisms in liquid whole egg, but also show that Salmonella types differ in their resistance to the lethal action of heat. Since most of the pasteurization runs were made with cell suspensions composed from several strains of a given type, it is not possible to state definitely that some strains are more heat resistant than others. However, in the case of *S. senftenberg*, a mixture of four strains which did not darken

x = not all killed

o = all killed

Kligler's iron agar was more resistant than a mixture of seven strains which produced a darkening effect.

The variations in the percentages of organisms killed at the same temperature and approximately the same time in repeated tests with the same *Salmonella* type may have been influenced by the variations in the cell concentrations of the inocula. Tanner and Dubois¹⁹ and Watkins and Winslow²⁰ have reported that the greater the concentration of bacteria in an inoculum

the more difficult it was to destroy all the cells. The numbers of *Salmonella* organisms used in these trials were greater than would likely be encountered in properly handled commercial liquid whole egg. Therefore, from the standpoint of numbers of *Salmonella*, the tests were conducted under more severe conditions than would normally be encountered in the commercial pasteurization of liquid egg.

It was impossible to maintain the exact temperature and time relation-

ships in different trials because of variations encountered in operation of the experimental pasteurizer. This was especially true at the two highest temperatures, 148° F. and 150° F. The higher the temperature and the longer the time of operation, the greater was the formation of film on the inside of the preheater tubes. This made it necessary to vary the temperature of the preheater and rate of flow through it in order to have the egg at a given temperature at the end of the preheater. Because of the difficulty encountered with film formation in the proximity of 150° F., it would be more practical to

pasteurize liquid whole egg for the destruction of *Salmonella* at a temperature of 140° F. to 146° F.

A mixture of different aged cells was used in order to represent more nearly the conditions likely to be found in commercial liquid egg. Robertson²¹ reported that, in general, cultures in the rapidly growing state were less resistant to heat, but after 20 hours remained fairly constant. Similar observations regarding effect of age on resistance have been made by others.^{22, 23}

The presence of *Salmonella* types found in hens' eggs and in hens' egg products is of considerable concern to

Chart 1. Pasteurization Temperatures and Times for Total Destruction of Some *Salmonella* in Liquid Whole Egg.

producers, to consumers, and to public health officials. A discussion of the significance is beyond the scope of this paper. However, it should be noted that several investigators^{6, 9, 24-27} have intimated that the types of *Salmonella* found in egg products may be responsible for cases of *Salmonella* food poisoning. Edwards²⁸ has called attention to the antigenic relationships of the *Salmonella* types found in fowls, in domestic animals, and in man. Bornstein²⁹ and others have also pointed out the lack of host specificity of many of the *Salmonella* types. Findings presented in this paper show that pasteurization is a practical and efficient method for destroying *Salmonella* organisms in liquid whole egg, thus reducing the potential public health problem.

SUMMARY

Temperatures and times necessary to destroy *Salmonella* organisms suspended in liquid egg and heat treated in a laboratory model pasteurizer were investigated. Each inoculum was prepared by compositing portions of 1 to 4 day old cultures of six to thirteen strains of a given *Salmonella* type. One hundred and sixty-four strains representing 16 *Salmonella* types commonly found in egg powder were used in the pasteurization tests.

Salmonella organisms were not difficult to destroy in the pasteurization unit. *S. senftenberg* and *S. cerro* were the most resistant types, and *S. pullorum* the least resistant. Strains of *S. senftenberg* which did not darken Kligler's iron agar were more resistant than those which produced a darkening of the medium.

With the two exceptions noted, the *Salmonella* types (*S. pullorum*, *S. oranienburg*, *S. montevideo*, *S. tennessee*, *S. anatum*, *S. bairdii*, *S. typhimurium*, *S. meleagridis*, *S. london*, *S. newington*, *S. derby*, *S. rubislaw*, *S.*

oregon and *S. kentucky*) were destroyed in liquid whole egg at 150° F. within 0.3 minutes, at 148° F. within 0.8 minutes, at 146° F. within 0.8 minutes, at 144° F. within 1.2 minutes, at 142° F. within 2.0 minutes, at 140° F. within 2.6 minutes, and at 138° F. within 3.7 minutes.

UNRRA Educational Program in China

Jerome Sidney Peterson, M.D., M.P.H., Assistant Professor in the Department of Preventive Medicine and Community Health, Long Island College of Medicine, and District Health Officer of the Red Hook-Gowanus Health Center, New York City Department of Health, has been granted a leave of absence of one year with the United Nations Relief and Rehabilitation Administration in China. Dr. Michael Antell, formerly District Health Officer of the Washington Heights Health Center, has been appointed to serve in Dr. Peterson's place during the forthcoming year.

While with the UNRRA-China Mission, Dr. Peterson will serve with the commissioned rank of Surgeon (R) in the U. S. Public Health Service. His assignment will include the teaching of

modern public health methods at the training center established at Chungking for physicians and other public health personnel from all parts of China. Dr. Peterson will also travel throughout China as Visiting Lecturer, to teach in the various regional centers which are now being developed. This educational program will emphasize the control of tuberculosis and other communicable diseases.

Dr. Peterson, who graduated from the College of Physicians and Surgeons, Columbia University, and received the M.P.H. degree from the Harvard School of Public Health, joined the Long Island College of Medicine Faculty in 1944.

Dr. Antell is an alumnus of the Long Island College of Medicine and also obtained the M.P.H. degree from the Harvard School of Public Health.

Need for a Public Health Program in Rheumatic Fever and Rheumatic Heart Disease*

DAVID D. RUTSTEIN, M.D.

City Department of Health, New York, N. Y.

THE prime objective of all public health programs is the prevention of disease, disability, and death. In surveying the field of unmet public health needs from the point of view of this objective, it is immediately obvious that rheumatic fever and rheumatic heart disease have never received the attention which they deserve from public health workers. In planning post-war public health programs it is imperative that adequate attention be paid to this disease entity.

The entity rheumatic fever and rheumatic heart disease has been selected as the subject of this presentation because it is the commonest cause of mortality and disability in children and young adults.¹ It is a chronic disease punctuated by acute episodes of fever and inflammation of various organs of the body, particularly the heart, joints, blood vessels, skin, and brain. The seriousness of the disease resides in the fact that death occurs during acute episodes, and because the majority of patients who recover from acute attacks have permanent heart damage—so-called rheumatic heart disease.

The disease usually has its onset in early childhood. The largest number of patients have their initial attack at about the age of 8, although initial at-

tacks not infrequently occur in adults. Attacks recur at frequent intervals until puberty is reached, at which time the attacks become less frequent. In this country the greatest seasonal prevalence is found in late winter and early spring. Rheumatic heart disease is the scar of acute rheumatic fever. The scar develops primarily on one of the heart valves, the mitral valve, and causes gradual obstruction to the flow of blood from the left auricle through that valve to the left ventricle. In addition the diffuse scarring of the heart muscle weakens that portion of the organ.

The prognosis of a patient who has had an attack of acute rheumatic fever may be learned from a study of the data compiled by Dr. T. Duckett Jones at the House of the Good Samaritan in Boston.² At that institution 1,000 children were followed for a period of ten years each, following the initial diagnosis of the disease (Figure 1). It was found that at the end of that period of time 203 were dead and 783 were living, 14 of the patients having been lost from observation. Of those who survived, 344 were forced by the residual heart disease to limit their activities; 135 of these were so incapacitated that they were forced to lead a sedentary existence; and 209 were restricted in that they could not participate in competitive sports. Only 439 were able to lead a completely normal existence. From our knowledge of the

nature of the disease it is reasonable to expect that further mortality and disability will occur after the first 10 year period.

Another indication of the severity of the disease is the diminished life expectancy of sufferers from this disease. In figures compiled by Hedley for the year 1936 in Philadelphia³ the average age at death of individuals with rheumatic fever or rheumatic heart disease was 36.5 years, in comparison to an

average age at death of 55 years⁴ for the general population of the same city in the same year (Figure 2).

The magnitude of the problem is great. The disease is a common one. Where surveys have been conducted, from 0.3 to 6 per cent of the childhood population, and from 0.6 to 1 per cent of the young adult population have been found to be afflicted with rheumatic heart disease.⁵ This is similar to the prevalence of tuberculosis. The

DATA COMPILED BY A.P.A.

entity rheumatic fever and rheumatic heart disease is the commonest cause of death between the ages of 5 and 19 and the second commonest cause of death in the age group of 19-24.¹ Swift⁶ has shown that the reported deaths from rheumatic fever and rheumatic heart disease in New York City in 1938 were 1,105 as compared with a combined total of 247 for pertussis, cerebrospinal meningitis, measles, diphtheria, scarlet fever, and infantile paralysis (Figure 3). In other words, in 1938 there were approximately five times as many deaths in this one disease as from a combination of six common reportable diseases in New York City in the same year.

Rheumatic fever has been a particularly prevalent disease in the military population during World War II. Figures released by the Office of the Surgeon General of the U. S. Army indicate that approximately 17,000 cases of rheumatic fever occurred in that branch of the service from January, 1941, until August 1, 1945.⁷ The Bureau of Medicine and Surgery of the United States Navy has indicated that from the onset of the war up to January 1, 1945, 14,344 cases of rheumatic

fever occurred in that branch of the service.⁸ During the same period the Office of the Air Surgeon has estimated that thousands of cases occurred in the air forces,⁹ although an exact figure has not been released. The majority of the attacks of rheumatic fever among members of the Armed Forces occurred in individuals who had no history of previous attacks of rheumatic fever. When one recognizes that rheumatic fever and rheumatic heart disease are chronic diseases, the expense to our government for the care of veterans who have acquired this disease while members of the Armed Forces may well be imagined.

During the past few years information has accumulated which has increased our knowledge of rheumatic fever. We have learned much concerning factors⁵ which may be nonspecific, such as poverty, crowding, climate, dampness, and the detonating effect of an infection with the group A beta hemolytic streptococcus. At the present time this knowledge is not adequate to assure prevention of the disease or its specific treatment. Further research is badly needed.

In spite of our relative lack of knowl-

edge, much can be done to lessen the burden of this disease on the individual and on the community. Surveys of communities have revealed that a large number of agencies are already concerned with the rheumatic fever problem.¹⁰ Such groups as practising physicians, hospitals and convalescent and foster homes, visiting nurse associations, organizations of medical social workers, school health agencies, housing authorities, private charitable organizations, local heart associations, occupational therapy services and governmental departments of welfare, education, and health are now concerned with the problem. In most communities these agencies are working earnestly, but in a completely haphazard fashion, with lack of coördination; and none of them individually is equipped to handle the entire problem. Since rheumatic disease is chronic, there is a tendency for patients to shop around and there is therefore endless duplication and waste in the use of community assets for the care of such individuals.

In addition to the administrative reasons already presented, there are a large number of clinical and epidemiological facts which indicate the need for the organization of a community rheumatic fever program. These include: difficulties in the diagnosis of rheumatic disease, the wide prevalence of the disease, the chronic nature of rheumatic disease with its impact on family life, the low economic level in which the disease is most prevalent, and the complexity of care necessary for the management of patients.

These individual factors deserve more detailed discussion. The difficulty of diagnosis of rheumatic fever is well known. Precise diagnosis is made difficult because the etiology of the disease is unknown, there is no specific diagnostic laboratory test, and the diagnosis in most cases is frequently dependent on a physician's impression of a group

of nonspecific symptoms and signs. Many diseases have been confused with it. Among these are tuberculosis, anterior poliomyelitis, functional heart disease, influenza or grippe, undulant fever, inflammatory joint diseases, including rheumatoid arthritis, and other febrile diseases. This has resulted in wide variations in the diagnosis of rheumatic fever by general practitioners.¹¹ These points emphasize the great possibility of error in falsely diagnosing the disease in normal people, and the failure to diagnose the disease in the rheumatic patient. It is a serious matter not to diagnose rheumatic disease when it exists, but it is an even greater tragedy to apply the rheumatic label to a perfectly normal child. One of the greatest benefits which may be expected from a community rheumatic fever program is the removal of the label of rheumatic fever from patients inaccurately diagnosed.

Precise diagnosis in early cases requires many laboratory aids and much clinical experience with the disease. Even when all of these facilities are available, the diagnosis may still be difficult, particularly in early cases. In the Cardiac Classification Service of the New York City Department of Health, where school children are referred by a school physician for consultation and examination by a qualified cardiologist, one-third of the individuals admitted to the clinic leave with a diagnosis of either possible heart disease, potential heart disease, or possible and potential heart disease.¹² In other words, it is not possible for a qualified cardiologist to determine on one visit in one-third of the cases whether or not rheumatic disease is present. In such instances it is necessary for the patient to return and to be followed carefully at future examinations in order to determine whether or not the disease actually exists. In most cases this can usually be determined after a relatively short

period of follow-up. The experience of the Cardiac Classification Service is typical of that found in cardiac clinics throughout the country.

The familial prevalence of the disease plus its chronic nature places a very great burden on the family. Patients are prone to have recurrent attacks of rheumatic fever and require special care between attacks. Furthermore, the development of rheumatic heart disease imposes crippling and limitation of activity in a sizeable percentage of the cases. The fact that more than one individual in the same family may become afflicted with the disease contributes to the low economic level in which the disease is most prevalent. This low economic level implies poor, crowded, and damp housing, poor nutrition, and the frequent occurrence of other diseases, particularly respiratory diseases, in the same family. Where these factors exist, rheumatic patients cannot be properly handled at home, and may need foster and convalescent home services.

With all of these facts in mind I should now like to outline the organization of a program. First, there is need for a central integrating agency where all community facilities for the care and diagnosis of patients may be pooled. The registry of known rheumatic patients should be maintained at this agency. Of all community agencies, the health department is best suited for the performance of this function, and it may operate in exactly the same fashion as it does in the case of other crippled children's programs. The registry of known patients and a file of community facilities are the tools with which the program is integrated.

The arguments in favor of a registry as against a reporting system in the case of rheumatic disease have been outlined elsewhere¹³ and will not be repeated in detail here. Briefly, it is felt that the requirement for reporting

of rheumatic fever by the practising physician is not a desirable one. Accurate information concerning the prevalence of rheumatic disease and a useful current file of rheumatic fever patients can be obtained in a much more satisfactory manner through the use of a registry such as that of the London County Council Rheumatism Scheme.¹⁴ Such a registry, complemented by a current file of available community facilities for the care of rheumatic fever patients, will provide a very satisfactory basis for program organization.

The next important need is medical service. Such service includes diagnostic, treatment, and follow-up facilities in the offices of private physicians, in clinics, hospitals, sanatoria, and convalescent homes. The use of the services of a cardiologist or of an approved cardiac clinic for the purpose of accurate diagnosis of this disease does not mean that the patient will leave the care of the private physician. On the contrary, the private physician should act as the initial screening agency, suspecting rheumatic fever whenever it may possibly exist. The consultant cardiologist or the approved cardiac clinic should then be available to him to provide him with accurate diagnosis of his case and with recommendations for proper follow-up of this chronic disease. Professional education of physicians should be directed toward lowering their threshold of suspicion of the existence of the disease and in verification or denial of the suspicion through the use of properly qualified consultants and clinics. The consultant and the clinic should also provide guidance to the physician in the complicated problem of prophylaxis against recurrences of the disease through the use of the sulfonamide drugs.

There should be available adequate facilities for case finding, particularly among siblings of known patients with

rheumatic disease. Such case finding services may be operated in collaboration with approved clinics. The organization of case finding services for rheumatic disease is similar to that of tuberculosis.

Nursing service will be necessary in clinics, hospitals, convalescent and foster homes, and in the home of the patient. Careful coördination of the activities of institutional and visiting nurses is essential.

Medical social service is important, since most patients suffering from rheumatic disease are in the lower income group. Such services should be designed to make community facilities fit the needs of the individual patient.

Provision should be made in the school health service for case finding, special classes, vocational guidance, and bedside teaching for institutionalized and bedridden patients. Where the cardiac damage is likely to cause permanent physical incapacitation, vocational therapy services are essential to aid the patient in becoming a useful citizen rather than a community liability.

Occupational therapy services will be necessary to maintain the morale of chronically bedridden patients.

It is necessary to plan and conduct a program of professional education for physicians, nurses, medical social workers, school teachers, and representatives of all agencies concerned in the rheumatic fever program. It is impossible to obtain complete coöperation on the part of the agencies concerned unless the agency representatives are familiar with the objectives and the plans of the program. Education of all these groups must, therefore, precede the organization of the program.

Lay education will be necessary to provide proper financial support for the program. Such education at first should be directed toward the general features of the disease and the magni-

tude of the problem. Education in the symptoms of the disease must await the development of proper diagnostic facilities. A great deal of anxiety in the minds of patients and relatives will be created if such education precedes the existence of such facilities. On the other hand, after adequate diagnostic facilities are established, lay education in the symptoms of the disease is important to assure a demand for medical care early in the disease.

There is a great need for additional information about rheumatic fever and rheumatic heart disease. Whenever possible the program should provide for research in the clinical and epidemiological features of rheumatic fever.

Finally, provision should be made for guidance and evaluation of the effectiveness of the program. Rheumatic fever programs are experimental, and the individual features of such programs should be carefully studied in order to determine whether or not they are necessary or need modification.

There are many details lacking in this outline of a community program. Some have been omitted because of the need for brevity. Many remain to be worked out. Coördination of rheumatic disease programs on a national level will facilitate this process and give impetus to the development of local rheumatic fever programs throughout the country. Since the coördination of a rheumatic disease program on a national level is so important, this presentation would not be complete without some reference to the American Council on Rheumatic Fever.

The need for coördination on a national level was recognized approximately two years ago when the American Heart Association called a conference of national organizations concerned with the problem of rheumatic disease. The American Public Health Association was one of the organizations represented at that conference. The members of the conference unanimously

adopted the following recommendations:

This conference is strongly in favor of the extension of public programs supported by federal, state, and local funds for the study, prevention, and treatment of this disease. Moreover, we believe it essential that additional funds be secured from private sources for the purpose of special studies to increase basic knowledge of the disease, for professional education, and for increasing public awareness of the problem.

In order to accomplish the purposes mentioned above, this conference recommends that a Council on Rheumatic Fever be formed under the leadership of the American Heart Association and that this Council shall include representatives of interested organizations.

Following the initial meeting, the American Council on Rheumatic Fever of the American Heart Association was formed, and included representatives of the following organizations: American Academy of Pediatrics, American Association of Medical Social Workers, American College of Physicians, American Heart Association, American Hospital Association, American Medical Association, American Nurses Association, American Public Health Association, American Rheumatism Association, and the National Society for Crippled Children.

The Council has been slow in getting under way because of difficulty in obtaining adequate financial support. This is due to the great lack of public awareness of the importance of the rheumatic disease problem. The initial program contemplated by the Council when funds are available is as follows:

1. Preparation of detailed plans for community rheumatic fever programs
2. Preparation and distribution of criteria for the diagnosis of rheumatic fever and rheumatic heart disease and of recommendations relating to treatment and convalescent care
3. Preparation of recommendations relating to undergraduate and graduate education of physicians and nurses
4. Plans for the initiation or sponsorship of research by individuals or groups

5. The preparation and adoption of a uniform method of evaluation of existing programs in rheumatic fever

The coöperation of the American Council on Rheumatic Fever with local voluntary and governmental public health organizations will do much to increase and codify our knowledge of the basic principles of community organization in the rheumatic fever program.

In summary, it is evident that the entity rheumatic fever and rheumatic heart disease poses a significant public health problem, and it is important that public health agencies meet this problem on the basis of established clinical and epidemiological facts in accordance with sound administrative principles.

Improvement of the Nasopharyngeal Swab Method of Diagnosis in Pertussis by the Use of Penicillin*

WILLIAM L. BRADFORD, M.D., ELIZABETH DAY, AND
GEORGE P. BERRY, M.D., F.A.P.H.A.

*Departments of Pediatrics and Bacteriology, The University of Rochester,
School of Medicine and Dentistry, Rochester, N. Y.*

IN 1929 Fleming¹ demonstrated the value of penicillin in the isolation of *Hemophilus influenzae*. When penicillin was incorporated in the culture medium or when an amount of from 2 to 6 drops of it was spread over one-half a Petri plate after the infected material, such as sputum or nasal mucus, had been streaked over the surface of the medium, the growth of the penicillin-sensitive organisms was so completely inhibited that *Hemophilus influenzae* often grew in practically pure culture. Fleming stated, "In addition to its possible use in the treatment of bacterial infections penicillin is certainly useful to the bacteriologist for its power of inhibiting unwanted microbes in bacterial cultures so that penicillin-insensitive bacteria can readily be isolated."

MacLean (1937)² used Fleming's technique for the isolation of *Hemophilus pertussis*. He applied from 6 to 8 drops of the strong penicillin solution to one-half of the Bordet's medium in a cough plate. Of 50 such plates exposed, 47 gave positive cultures for *Hemophilus pertussis* on the penicillin-treated side of the plate as against 33 positives obtained on the untreated side. When

pharyngeal swab cultures, taken after a paroxysm, were treated with penicillin, from 75 to 80 per cent yielded positive results.

Cruickshank (1944).³ applied 4 drops (15 to 25 Oxford units) of penicillin solution to the surface of Bordet's medium (12 ml. of medium per plate). Later, this amount was increased to 8 drops. The solution was distributed over the surface of the plate with a sterile glass spreader. After the plate was incubated for from $\frac{1}{2}$ to 1 hour, it was inoculated with material obtained by swabbing the posterior pharynx with a bent swab passed through the mouth. Cruickshank found that such swab cultures were equally as effective as ordinary cough plate cultures without preliminary treatment with penicillin. He indicated that more care in the taking of the post-nasal cultures would probably have given better results.

The nasopharyngeal swab method for bacteriological diagnosis of pertussis, introduced in 1940, has proved to be superior to the ordinary cough plate method in our hands.^{4, 5} This superiority has been confirmed by others.^{6, 7} In using this technique a small loopful of 0.85 per cent sodium chloride solution is placed upon the surface of the medium and the charged swab is passed

* This work was supported in part by grants from the John and Mary R. Markle Foundation and from The Chatterbox Fund.

FIGURE 1—Showing the inhibiting effect of penicillin on the growth of contaminating organisms (right) to facilitate the identification of *Hemophilus pertussis* colonies on the surface of Bordet's medium. (Control plate is shown on the left)

back and forth several times through the drop of saline. The plate is then streaked with a long, flexible loop.

In the present report are described the results of a series of cultures in which a loopful of penicillin solution containing 1,000 Oxford units per ml. was substituted for a loopful of 0.85 per cent sodium chloride solution. For comparison, cultures were taken chiefly from hospitalized patients during various stages of whooping cough, and plated simultaneously by the two methods.

RESULTS

The results shown in Table 1 clearly indicate that the use of penicillin facilitates the isolation of *Hemophilus pertussis* by inhibiting the penicillin-sensitive organisms that ordinarily appear on cultures made from the posterior pharynx.

The area of inhibition of the contaminating organisms, as usually observed, is well illustrated in Figure 1. Within this area a practically pure growth of *Hemophilus pertussis* is often observed. Moreover, the medium within this zone usually retains its original

TABLE 1

Results of 95 Simultaneous Nasopharyngeal Swab Cultures from 52 Cases of Pertussis

Age Years	Number Patients	Number of Positive Cultures	Number of Negative Cultures
Penicillin			
Under 2	20	47	2
2-14	28	38	1
Over 15	4	7	0
Total	52	92 (97.6%)	3
0.85% NaCl			
Under 2	20	42	7
2-14	28	26	13
Over 15	4	7	0
Total	52	75 (76.8%)	20

Ratio of difference in Percentages to its S.E. 4.5 to 1

cherry-red appearance. After 3 days of incubation, the remainder of the medium is frequently discolored by the acid producing growth of contaminating organisms.

When too strong a concentration of penicillin is used, the growth of *Hemophilus pertussis* is inhibited. In spite of the fact that the organism is generally considered to be penicillin-

insensitive, our observations indicate that it is sensitive to strong concentrations. This effect occurs *in vivo* as well as *in vitro*, for we have observed in certain experiments a significant clearing of the organism from the lungs of experimentally infected mice treated with penicillin.

Two interesting, and probably significant, findings appear in our data. First, the penicillin treated cultures gave better results than the saline treated cultures in the age groups above infancy (Table 1). (The superiority of the nasal swab method was originally observed to exist in cultures taken from infants.) Second, such cultures are more efficient after the catarrhal period of the disease (Table 2); for example, 13 of the 20 negative control cultures were obtained in the later stages of the disease when the number of organisms is usually less.

TABLE 2

Distribution of Negative Cultures According to the Stage of the Disease

Stage of Disease	Number of Negative Cultures	
	Penicillin	0.85% NaCl
Catarrhal (1st and 2nd week)	2	7
Paroxysmal (3rd and 4th week)	1	7
Decline (5th and 6th week)	0	6

SUMMARY

By means of a technique in which a charged post-nasal pharyngeal swab was moistened with a loopful of penicillin (1,000 Oxford units per ml.) and placed upon the surface of Bordet's medium, a high percentage (97.6 per cent) of positive cultures of *Hemophilus pertussis* was obtained from patients in various stages of whooping cough. Cultures taken in the same way except for the substitution of 0.85 per cent sodium chloride solution for the penicillin, yielded a significantly lower percentage (76.5 per cent) of positive cultures.

Post-war Training Problems in Public Health*

GEORGE T. PALMER, DR.P.H., F.A.P.H.A.

Senior Sanitarian (R), U. S. Public Health Service, Washington, D. C.

A LETTER recently received by the Public Health Service reads in part as follows:

"Please send me a list of full- and part-time public health positions available to physicians about to be discharged from the armed forces. I am a pediatrician and want to get into public health work."

Another letter reads as follows (this is from Iwo Jima):

"I have served in the hospital corps of the Navy over three years, during which I received a course of instruction in malariology at the Navy Medical School. I have been overseas working with a malaria and epidemic control unit for 15 months. I have had two years of university training. Any information that you can send me that will help me plan a career in public health will be greatly appreciated."

These two letters, selected from many, indicate one of several reasons why Surgeon General Parran believed it necessary to appoint a Committee on Post-war Training of Public Health Personnel.

The first letter is from a physician. He wants to get back into the public health field. But where? What are the openings? The second letter is from a pharmacist's mate, first class, who has had some college training. For several years he has been engrossed in a very practical and useful job, malaria control. Where does he fit into the

civilian public health picture? Is there some way we can salvage this valuable experience? Should he seek a health department connection in a community that has a malaria problem? Or should he go back to college and get his degree? There is no malaria problem in his home state. His talents are most needed in the South. But to get a job in some areas of the South or in some areas in the North or West for that matter, he must be a resident of the state. What then? If he decides to go back to school, he can get some financial aid through the G-I Bill of Rights, tuition up to \$500 a year and subsistence allowance up to \$90 a month. But with a wife and two children, he must think twice.

The pharmacist's mate needs more schooling if he wants to advance in the public health field. He has had some practical training.

The pediatrician needs professional training in a school of public health if he expects to go into public health work as a career. The pediatrician is the more fortunate one. He has not only his G-I Bill of Rights financial aid, but he also is in line for federal grant-in-aid funds which the states can spend for professional training, and which can be used to supplement the G-I Bill of Rights allowance up to a top of \$250 a month. But he must first be appointed to a state or local health department to be eligible for grant-in-aid funds. There may or may not be a vacancy in his home state. And even if there were a

* Presented before the Victory Meeting of The Public Health Association of New York City in collaboration with The American Public Health Association in New York, N. Y., December 13, 1945.

vacancy, his home state may not have asked for funds for training a physician in a school of public health. What then? Cannot the Public Health Service provide grant-in-aid funds for a fellowship? No, the grant-in-aid funds are for allotment to the states. If the state does not ask for funds for training, then there is no way for the Public Health Service to use these funds for training.

Inquiries of this nature are important, and there have been hundreds of them coming in to the Public Health Service and the American Public Health Association, which is coöperating with the Service in this program. The solution of the problems raised by these letters is even more important. They are important because the state and local departments of health in this country are desperately in need of trained personnel.

The Public Health Service made a survey of these departments in the summer of 1945. This discloses that of 29,000 established positions, 6,500 vacancies existed. Forty-five per cent of these vacancies are being held for former employees who went into the armed services. The remaining vacancies, numbering 3,600, call for new personnel. Among these new persons needed in state and local health departments are 2,000 public health nurses, 425 health officers and medical administrators in special fields, 140 public health engineers, 400 laboratory workers, and 400 sanitary personnel other than engineers.

But even more new people are needed than shown above. Public health workers in health departments are retiring each year as they reach the age limit, and even younger people are leaving the field from time to time for one reason or another. Thus we need annual replacements. The exact number is unknown, but at the minimum it would be at least 1,700. Nor have we

included above the new persons who will be needed as public health work expands, nor the new individuals and replacements needed in voluntary health agencies and in school health work carried on by boards of education. Thus instead of 3,600 new persons who are known to be needed in state and local health departments as disclosed by the aforementioned survey, the total number of new personnel to whom public health is beckoning is nearer six or seven thousand.

Another reason why these letters from distant military camps in this country and from Iwo Jima, Okinawa, the Philippines, Hawaii, and elsewhere are important is that this present period of demobilization offers an unprecedented opportunity to recruit staff for public health. Many men and women, particularly those who entered the military service directly from college or medical internship or dental, nursing, and engineering schools, are poised on the brink of a decision as to their future career. The present is a dividing line between a war era and an era of welcomed peace. What to do? Now is the unique time to make known to returning veterans the needs and the attractions of a public health career.

But public health calls in the main for professionally trained persons. The untrained person who enters the field will find himself thwarted as the years roll by and as he looks forward to advancement and salary increase to solve the worries of a growing family, increased expense, and responsibilities. Professional training will facilitate the climb up the ladder.

There is already a surge to training institutions. The G-I Bill of Rights will help in the financing, and for employees of state and local health departments, the federal grants-in-aid to states will also help in professional training. But for men and women just out of the military service, who have

never been employed in state or local health departments and who want to enter this field, the grant-in-aid funds are not so widely available. Questions of residence, the number of existing vacancies in an individual state, and available funds for training in the specific state enter the picture. The applicant is sometimes blocked in finding an opportunity for training.

In order to surmount these obstacles the private foundations have been asked to lend their assistance with fellowships for the next two years so that the orderly flow of eager applicants to professional training institutions may not be obstructed and the full advantage of this unusually favorable period for recruitment may not be wasted.

If so many flock to training institutions—will there be room for all? Have we the capacity to absorb the load? The capacity of the eight schools of public health in the Association of Schools of Public Health is estimated to be less than 500 students as candidates for the degree of Master or Doctor of Public Health, and 500 more with other types of training, including short-term courses. The probable load of degree candidates may be estimated as 600 a year for the next three years, after which it may lighten somewhat. This includes about 260 physicians to be trained annually as health officers and administrators of special services.

There are 2,000 positions in public health nursing to be filled by new staff in state and local health departments alone. This number, together with replacements for nurses retiring or leaving positions in state and local health departments, as well as local boards of education and voluntary agencies, raises to 3,500 the number of positions which should be filled before another year. Schools of public health nursing will be faced with the task of training between 2,000 and 3,000 nurses annually in the years immediately ahead.

The Surgeon General's Committee is acting as a clearing house, trying to establish a through connection between demobilized veterans on the one hand and training and jobs on the other. But establishing such connection is not enough. The committee believes that the training problem itself deserves much thought. What kind of training? How much training? Should academic professional training, at least for a physician, be preceded by an orientation period of training? Here the trainee working temporarily in a state or local health department under supervision but without administrative responsibilities, can have a chance to learn the problems, to get the feel of the job, and to see whether he is going to like it. Here, also, the potential employer can size up his prospective employee to see whether he is worth an additional investment in professional public health training.

Academic professional training is essential, but it is a sheltered life. While the student health officer has been acquiring his master's degree in public health, presumably he has been given the theoretical instruction on how to swim in both the charted and uncharted waters which he may encounter. Would it not be a good idea for him to practise swimming for a while under close supervision in a going health department and have a try at buffeting the waves of practical situations and realistic health administration before being turned loose to be skipper of his own crew and master of his boat? Field training smooths the path between the vine covered buildings and the administrative vocation of health officer.

Even what goes on within the college walls has been discussed by the committee. What subject matter should be taught in a school of public health? Years ago, Charters and Hindman,¹ after a detailed study concluded that the duties of a public health commis-

sioner "seem preponderatingly to be administrative, executive, educational, and personal." In the training of health officers, they state further that "those duties will have preference in a curriculum which have the widest range, occur most frequently, are most difficult to learn, and are of most crucial importance when they do occur." The Surgeon General's Committee—which includes the deans of two schools of public health—has a feeling that such subjects as health education (adult and school), personnel administration, business administration and administration of medical care programs have yet to be given adequate attention in the curriculum.

The schools of public health are performing a magnificent service not only for the local students but for students who come from all states and from many foreign countries. These schools are rendering a service to the nation, for their students are being trained primarily for public positions to protect the health of the nation. They are contributing to good international relations in the training for leadership that is being given to foreign students. But they lose a thousand dollars annually on every degree student. Federal aid directly to the schools themselves to

help support their faculty and administration would be fully justified.

There is a big job ahead of us in the next few months. It calls for the closest coöperation between public and private health agencies on federal, state, and local levels. The keen interest of the schools of public health is a necessity. Financial support from the foundations to meet the emergency problems is needed. The steps already taken are beginning to bring results—not many as yet—but enough to show that we are on a promising course.

Another letter, this one from a physician mustered out after four and a half years in the Army, is an example of what I mean.

"My application has been accepted at the School of Public Health. I am happy to say that I shall be starting school there in a few days. After I get my degree, I shall want to write you again for further advice."

In this instance, a through connection has been established between the demobilized veteran and his training.

Results from the Current Mortality Sample

ELIZABETH H. PITNEY, PH.D.

Vital Statistics Division, Bureau of the Census, Washington, D. C.

AS 1945 came to an end, the United States could chalk up on the credit side of its vital statistics ledger for the year freedom from major epidemics, a continuation of general mortality at a level comparing favorably with that for the previous year, and a further reduction in the mortality from a number of the important causes of death. Despite the high wartime birth rate and the heavy load carried by hospital personnel and facilities, both the infant and maternal mortality rates gave promise of reaching new record lows in 1945. The death rate for respiratory tuberculosis which had been watched apprehensively since the beginning of the war continued its almost unbroken decline into 1945. In the winter of 1944-1945, the death rate for pneumonia approached, if it did not actually reach, an all time low for the season. Of the infectious diseases common in childhood, the death rate for measles reached a cyclical low and that for cerebrospinal meningitis, which had been in epidemic phase for the two preceding years, dropped in 1945 toward the trough of its periodic cycle. Deaths from accidents other than motor vehicle accidents, which had increased among males at the beginning of the war, declined in 1945, a part of the decrease being due to a sharp reduction in deaths from air transport accidents among men in military training.

On the other side of the ledger, the most dramatic change occurred in the

death rate for motor vehicle accidents. In relation to its wartime level, the death rate for motor vehicle accidents rose in 1945, slowly at the time of VE-day and rapidly following VJ-day and the end of gasoline rationing. By October the rate was about one and a half times as high as in the same month of 1944, and the outlook for the first year of peace was the highest motor vehicle accident death rate since 1942. There was also some indication that the decline which occurred in the death rate for suicide during the war (from 14.3 per 100,000 population in 1940 to 10.0 in 1944) came to an end in 1945.

These observations regarding some of the significant developments in mortality in the United States during 1945 are based upon the provisional figures which were obtained from a 10 per cent sample of death certificates. A final accounting of all registered deaths in the country will be available toward the end of 1946 when the records for all registered deaths have been received and tabulated in the Bureau of the Census.

The program for obtaining cause-of-death statistics for the United States on a current basis by means of sampling was set up in 1942 by the Bureau of the Census with the coöperation of state and city* vital statistics offices. In 1943 the sampling area included 46

* The four independent registration cities are Baltimore, Boston, New Orleans, and New York.

states and the District of Columbia, and in 1945 it covered the entire continental United States. The purpose of this paper is to describe the program and its results.

HOW THE SAMPLE IS TAKEN

In the ordinary course of events, vital records flow from their points of origin in the local registration districts where the births or deaths occur into the state vital statistics offices and thence in the form of copies or transcripts to the Bureau of the Census. In most states, shipments of certificates from the local registrars arrive monthly in the state office, the local registrars being required by law to send in by the 10th of each month the certificates that were filed with them during the previous month. After the certificates have been queried and processed for state use, they are copied for the Bureau of the Census. When transcripts of all registered deaths occurring in a calendar year have been received in the Bureau, usually by the fifth month of the following year, tabulations can be made on a national basis.

The current mortality sampling program taps this stream of vital records in the state office on about the 20th of each month. The certificates drawn in the sample are copied immediately and the transcripts are sent to the Bureau of the Census where the processing of the data is given high priority so that the results may be released for use within less than 2 months from the close of the period in which the deaths occurred.

The sample is taken by selecting every tenth death certificate received between two dates a month apart.¹ In most states, on the sampling date, the certificates that have been received are together in a temporary file, arranged in a definite order usually by county or registration district. The sample is then drawn by taking every tenth death certificate in the file.

The monthly sampling date is set for the time at which it can be anticipated that practically all local registrars will have sent in their certificates for the previous month. Thus, it may be expected that the group of certificates received between two sampling dates, say the 20th of March and the 20th of April, will consist almost entirely of certificates for deaths occurring in March. Usually some certificates for deaths in earlier months will be included and some for March deaths will be missing. However, it has been found that the stragglers for earlier months tend to balance those for the current month still outstanding,² so that no serious error is involved in taking the data received between two sampling dates as an index of the events which occurred during a calendar month.

CURRENT MORTALITY ANALYSIS

The tabulated returns from the sample are published monthly in a four page release, *Current Mortality Analysis*. This regularly includes a graphic presentation of the results as well as a discussion of the returns for the month and several tables giving the number of deaths in the sample and death rates by cause and by age and race for the United States and its major subdivisions.

The question of how the returns from the sample may be presented in a useful form is of great importance. One of the chief functions of current mortality statistics is to give prompt warning of any change in the underlying force of mortality in the community. However, it may be hazardous in the extreme to draw any conclusion on the basis of a single month's rate. While 95 times out of 100 the month's death rate for cancer in the United States may be estimated within 6 per cent of its actual value, for a number of causes it may be necessary to estimate the rate from so small a number of deaths that by chance alone the estimate could

Variation Chart Showing Actual, Expected and Expected Variation of Death Rates from Influenza from Mortality Sample for United States for November, 1944–November, 1945

deviate from the actual rate by 50 per cent or more of its value.* Further, recognizing that even the complete death experience in an area during a given period of time is still only a sample of an underlying infinite universe, representing the forces of mortality in the community, account must also be taken of the "normal" variation in the monthly rate, that is, the fluctuation which cannot be attributed to epidemic or cyclical origin or to secular or seasonal movement.

Extensive use is made in *Current Mortality Analysis* of a type of graph which has been named "variation chart." Its purpose is to enable the reader to take in at a glance, and in relation to a base, the movement of the death rate over a period of some months and to assist him in evaluating the significance of a deviation in the current rate from this base.

As may be seen in the figure, a variation chart has three chief elements. These are: (1) dots which represent the

values of the monthly death rates as estimated from the sample, (2) a heavy central line which represents the "expected" rate, and (3) a shaded band which is intended to indicate the range about the expected rate within which the rate estimated from the sample may vary without necessarily implying a change in the underlying force of mortality.

The methods used in constructing the variation charts and the assumptions on which they are based have already been described in some detail.³ However, it may be said here that the expected rate for a cause for a particular month and year is obtained by projecting the long time upward or downward movement found in a time series of death rates for that cause and applying to the projected trend value an index of seasonal variation. For causes displaying a marked secular trend, the expected rate has a marked advantage over some average of past experience such as a median or mean as a base with which to compare the current rates obtained from the sample. The limits of the shaded area, computed from estimates of both the sampling variance and the

* In practice, the sampling variance is computed from the formula for a random sample taken without replacement.

"normal" variance,* are designed as far as possible so that under normal circumstances a rate will fall only infrequently above the upper limit.

EVALUATION OF THE RETURNS FROM THE SAMPLE

A continuous evaluation of the returns from a sample drawn in 53 separate offices is of the utmost importance. Fortunately a considerable measure of control can be exercised over the sampling process currently as the sample transcripts are received in the Bureau.

The two most common errors in taking the sample are: (1) the drawing of a number of certificates equal to 10 per cent of the deaths plus stillbirths instead of 10 per cent of the deaths alone (an error which may occur in situations where the records of stillbirths are filed with the certificates of death), and (2) taking 1 out of 10 of the certificates for deaths occurring in the current month instead of one-tenth of all the certificates received regardless of the month in which death occurred. The first type of error, giving too large a number in the sample, may usually be discovered by comparing the number of transcripts in the sample with the total number of deaths reported concurrently for the *Monthly Vital Statistics Bulletin*. The second type of error, causing the number in the sample to be too small, becomes apparent when the transcripts are distributed by month of occurrence of the deaths.

In contrast with the majority of sampling situations in which the parameters of the population are never known, the returns from the current mortality sample may be matched in due course of time against the 100 per cent statistics as finally tabulated. The table gives the number of deaths for

various causes, as estimated from the sample, for 44 states and the District of Columbia in 1943 and the corresponding numbers for the same area as tabulated from all registered deaths for the year.

Good agreement is found between the estimated and the final numbers of deaths for the majority of causes listed in the table. Among these are the infectious enteric diseases, the several infectious diseases common in childhood, tuberculosis, influenza, cancer, pellagra, the puerperal causes, and possibly diabetes and syphilis.

On the other hand, the number of deaths for several causes as estimated from the sample are found to differ significantly from the number as finally tabulated. The 1943 sample yielded an overestimate of the number of deaths for pneumonia and for the group of diseases of the cardiovascular-renal system. While the differences may not appear large (less than 3 per cent in the case of pneumonia and about 1 per cent for the cardiovascular-renal group), they are greater than could safely be attributed to chance ($P = < .05$). Further, the 1943 sample yielded underestimates of the number of deaths from suicide, homicide, motor vehicle accidents, and all other accidents.

A deficiency in the number of deaths in the sample from violence and accidental causes was not unexpected in the first year of the sampling program. Where the determination of the cause of death is a subject for a coroner's inquiry, there is necessarily a lag between the date of death and the time at which the certification of the cause of death reaches the state vital statistics office. Consequently, in those instances where provision is not made in the regular office procedure, great care is required to make sure that every certificate for a death from violence or accident has an opportunity to be sampled. The excess in the number of deaths in the sample

* A third term has been included which in most instances represents a negligible proportion of the total variance represented in the shaded area.

TABLE 1

Number of Deaths from Selected Causes, Tabulated from Final Figures and Estimated from the 10 Per cent Mortality Sample: 44 States¹ and the District of Columbia, 1943

(Place of Occurrence)

<i>Cause of Death</i>	<i>Final</i>	<i>Estimated</i>	<i>Percentage Difference</i>
All causes	1,324,917	1,327,560	0.2
Infectious enteric diseases	12,285	12,610	2.6
Typhoid and paratyphoid fever	555	590	6.3
Dysentery	1,339	1,480	10.5
Diarrhea and enteritis	10,391	10,540	1.4
Prevalent diseases of childhood	10,476	10,500	0.2
Cerebrospinal meningitis	2,790	2,760	-1.1
Scarlet fever	422	450	6.6
Whooping cough	2,811	2,890	2.8
Diphtheria	948	940	-0.9
Measles	1,171	1,280	9.3
Poliomyelitis	954	990	3.8
Acute rheumatic fever	1,380	1,190	-13.8
Tuberculosis (all forms)	50,756	50,920	0.3
Malaria	425	560	31.8
Syphilis	14,589	15,260	4.6
Pneumonia and influenza	80,747	83,120	2.9
Pneumonia (all forms)	65,643	67,420	2.7
Influenza	15,104	15,700	3.9
Cancer and other malignant tumors	153,923	154,140	0.1
Diabetes	33,916	34,980	3.1
Pellagra	845	930	10.1
Diseases of the cardiovascular-renal system ²	601,106	607,080	1.0
Puerperal causes	6,219	5,960	-4.2
Suicide	12,708	11,690	-8.0
Homicide	5,447	4,970	-8.8
All accidents	88,385	83,940	-5.0
Motor vehicle accidents	21,371	19,280	-9.8
All other	67,014	64,660	-3.5
All other causes	253,090	250,900	-0.9

¹ States excluded are: Arkansas, Georgia, Minnesota, and Texas.

² Excludes arteriosclerosis and high blood pressure (idiopathic).

from pneumonia and diseases of the cardiovascular-renal system may likewise be traced to specific errors in taking the sample. It is fortunate that this is so, for where a bias is due to an error in taking the sample, the error can be localized and the bias eliminated or reduced. It may be of interest to mention that in two instances the error in sampling was discovered before the data became available for this comparison.

BY-PRODUCTS OF THE SAMPLE

Since the sample contains all the detail available in the 100 per cent statistics, and since the sample design permits classification of the data along any axis, the use to which the sample has

been put extends beyond its primary function of giving prompt intimation of gross changes in the death rate for a specific cause. The punch cards accumulated from each month's sample have been combined in various ways and reshuffled for various purposes.

One purpose is to supply federal and other agencies with current statistics beyond those regularly published in *Current Mortality Analysis*. Special tabulations are regularly run each month for a number of federal agencies and others have been made upon request.

The flexibility of the sample, its relative cheapness, and the promptness with which it can be utilized, make it pecu-

liarily adapted for use in situations where it would be impractical, if not impossible, to obtain the required data from the regular tabulations of the 100 per cent statistics. To incorporate an additional item in the regular tabulation program involves not only the cost of coding and punching the item for almost one and a half million records, but requires that it be planned for about a year and a half in advance. Within the limits imposed by the sampling error, the same results may be obtained from the sample, with little delay, and often at less than one-tenth of the cost. This was illustrated on the occasion when the question arose in connection with a pressing administrative problem as to what proportion of the persons dying in each state had been born in that state. To obtain the information, all that was necessary was to take the sample data for 2 months, code and punch state of birth, and retabulate the cards.

At the present time, a number of special items which are not included in the program for tabulating all registered deaths are being coded and punched regularly from the sample returns.

These are: year of birth, length of stay in hospital or institution, associated cause of death, and state of birth. Year of birth is punched for the purpose of obtaining factors required in the construction of life tables, which may be used in distributing the number of children dying at each year of age according to the two possible years of birth. The item, length of stay in hospital or institution, has been introduced for the purpose of determining whether it is sufficiently well reported that it could be used in studying the relation of length of hospitalization to cause of death and to type of institution. In punching the associated as well as the primary cause of death it is hoped that it will be possible to collect in time a useful body of data on the characteristics of those decedents whose deaths are attributed to more than one cause.

The Whole Person

"Today when the medical profession has just about abandoned the effort to cure people by applying specific remedies to their various 'symptoms' and has about learned to think of the organism as a whole, the operation of many specialized health agencies produces

essentially the effect of dealing with isolated aches and troubles rather than with the whole person, to say nothing of the whole public."

Gunn-Platt Report, *Voluntary Health Agencies*, National Health Council, 1945.

A Group of Paracolon Organisms Having Apparent Pathogenicity*

L. A. BARNES, COMMANDER, H(S), USNR, F.A.P.H.A., AND
W. B. CHERRY, LIEUTENANT, H(S), USNR

Enteric Pathogen Laboratory, Naval Medical School, Bethesda, Md.

THERE is a large number of heterogeneous coli-like organisms which, having certain physiological characteristics unlike typical *Escherichia*, have been grouped together as paracolon bacilli.¹ Taxonomically they may be considered as occupying a position intermediate between the typical coliforms and the salmonellas.² A few sub-groups of paracolon organisms have been described and their importance noted.²⁻⁴ It is the purpose of this communication to describe briefly the characteristics of another sub-group of paracolon bacilli isolated during a small outbreak of gastroenteritis.

FEATURES OF THE EPIDEMIC

On May 13, 1944, it became apparent that an unusual number of cases of diarrhea were occurring in certain wards of a United States Naval Hospital and investigative procedures were instituted; clinical and epidemiological information was obtained by interviewing 219 patients and staff members. The illness was relatively mild. Only 1 of the 52 patients who were attacked exhibited blood in the stool, while 1 other had fever that was attributable to the disease. In almost all cases recovery was complete within 12 hours; 92.3 per cent of the

cases had diarrhea, the number of diarrheal stools per case averaging 4.8. Percentages of patients with other signs and symptoms were: abdominal cramps, 75.0; nausea, 50.0; and vomiting, 11.5.

Statistical analysis implicated corn pudding as the probable vehicle of the etiologic agent. It was found that this "left-over" food had been substituted for rice in the evening meal the previous day and that it was sent on food carts to the wards affected. As is the case all too frequently, no samples of the corn pudding were available for bacteriologic study. The incubation period averaged approximately 12 hours after eating the suspected food.

BACTERIOLOGIC STUDIES

Stool or rectal swab specimens for culturing were secured from 17 of the 52 patients; both types of specimens were obtained from 2 subjects and all 4 yielded positive results. All specimens were plated directly onto Difco SS agar and B-B-L Desoxycholate-Citrate agar and also were inoculated into the modified tetrathionate enrichment medium of Kauffmann.⁵ After 18 to 24 hours' incubation at 37° C. apparently non-lactose-fermenting colonies were transferred from the plates to agar slants, and plates of SS agar were streaked from the tetrathionate broth cultures. The following morning suspicious colonies were picked from these plates. In all, 28 single-colony

* The opinions or assertions contained herein are the private ones of the writers and are not to be construed as official or reflecting the views of the Navy Department or the Naval Service at large.

cultures of the organisms to be described were obtained from 12 of the 17 patients. No other cultures thought to bear an etiologic relationship to the outbreak were found.

Fermentative characteristics of the cultures were studied in glucose, lactose, sucrose, mannitol, xylose, maltose, rhamnose, dulcitol, arabinose, inositol, trehalose, salicin, sorbitol, cellobiose, adonitol, levulose, galactose, mannose, inulin, glycogen, raffinose, milk, and d-tartrate. In addition, the Imvic reactions and hydrogen sulfide production were determined and motility was studied in semi-solid agar.⁶ The results of these studies are as follows:

Acid and gas produced in 1 day (all cultures): glucose, mannitol, maltose, rhamnose, dulcitol (one strain remained negative for 23 days), arabinose, trehalose, sorbitol, levulose, galactose and mannose.

Delayed production of acid or acid and gas (all cultures): lactose (2 to 6 days); cellobiose (4 to 9 days).

No visible reaction in 21 days or more (all cultures): inositol, adonitol, inulin, glycogen, and raffinose.

Variable reactions: sucrose, 8 strains were negative for 21 days but the balance produced acid and gas in 1 day; xylose, 3 strains produced no change in 21 days while the remainder produced acid and gas in 1 day; salicin, 11 strains formed a slight amount of acid or acid and gas in 10 to 21 days but the other cultures remained negative for at least 3 weeks.

In B-C-P milk all strains produced a slight acidity that increased slowly during the period of incubation and eventually 5 cultures produced coagulation; all cultures tested were positive in d-tartrate. All cultures produced large amounts of H_2S , were actively motile, and the Imvic reactions for those studied were —+—+; Koser's citrate solution was the medium used in the last test. Gelatin was not liquefied by

any culture during 10 days' incubation. As can be seen, observations made early in the period of incubation of the cultures show a similarity to the characteristics of the *Salmonella* group but further incubation elicits the traits typical of the paracolon organisms.

In order to test the pathogenicity of the cultures, 5 different strains were injected intraperitoneally into white mice in a dosage of 0.5 ml. of saline suspension prepared from agar slants. Three groups of 3 mice each received sucrose-positive strains and 2 groups of 3 mice each received sucrose-negative cultures. Thirteen mice were dead within 24 hours after injection and the other 2 were obviously ill. Cultures made from the heart's blood of the 9 mice which were autopsied yielded pure cultures of organisms having biochemical reactions identical with those injected.

Drug susceptibility of 1 sucrose-negative and 1 sucrose-positive strain was demonstrated by complete inhibition of growth of the organisms when streaked onto plates of agar containing 5 mg. per cent of sulfathiazole; 1 mg. per cent of the drug in agar resulted in 70 to 90. per cent inhibition of growth.

SEROLOGIC STUDIES

Antisera were prepared in rabbits for one of the sucrose-negative and one of the sucrose-positive strains, using formalinized broth cultures as antigens. Sera with high titers for homologous H antigens were obtained. Of some interest, however, is the fact that while use of the sucrose-negative strains resulted in a very high titered serum for the O antigen, the sucrose-positive strain was weakly antigenic in the single rabbit used. Alcohol-heat prepared O antigens⁶ of 23 of the 28 strains reacted strongly with appropriate dilutions of both sera. Strangely enough, 5 sucrose-negative strains reacted only with the sucrose-positive serum. For-

malinized broth cultures of 24 strains used as H antigens⁶ agglutinated well in a 1:1,000 dilution of serum for the sucrose-negative strain, while 4 strains reacted only with serum for the sucrose-positive strain; no strain reacted with both sera at a dilution of 1:1,000. It appears, therefore, that these epidemic strains are serologically related; their exact relationship to each other and to other Enterobacteriaceae will depend upon extensive antigenic analyses.

Blood samples obtained from 10 of the patients on the second day and from 5 of the same patients on the tenth day following the outbreak failed to reveal significant agglutinin titers when the sera were tested against 3 of the strains. Unfortunately it was not possible to continue these tests further but it is unlikely that agglutination titers would have shown appreciable increases since the illness was transient and there was no evidence of blood invasion.

INCIDENCE AND DISTRIBUTION

Subsequent to the recognition of this paracolon sub-group additional strains have been identified; they have been isolated from subjects who were asymptomatic at the time of culturing, from sporadic cases of diarrhea, and at least one other epidemic. In the two latter categories evidences of etiologic relationships were strong. Further details concerning the known distribution of the organisms will be given in a later report.

SUMMARY AND CONCLUSIONS

A group of biochemically and serologically related organisms was isolated from patients during a small outbreak of mild gastroenteritis; the disease was self-limited and of short duration. The organisms that appear to have been the etiologic agents possess characteristics that at present classify them as paracolon bacilli; until a more systematic scheme of classification is evolved these cultures are designated as paracolon (Pc.) 100-5-13. Clinical, epidemiological, biochemical and serological features are described briefly.

ACKNOWLEDGMENTS—The authors desire to express their indebtedness to the following: Lieutenant Commander F. S. Cheever, (MC), USNR., under whose direction the staff of the Department of Epidemiology carried out the epidemiological and statistical investigations; Lieutenant Commander Paul V. Woolley, Jr., (MC), USNR., Department of Bacteriology who supervised the testing of certain strains for susceptibility to Sulfathiazole; and, Dr. P. R. Edwards for reading the manuscript.

BARNES, H(S), USNR, F.A.P.H.A.

Naval Medical School, Bethesda, Md.

ALTHOUGH there are various reports of outbreaks of gastroenteritis in which species of *Proteus* were at least circumstantially involved,^{1, 2} with certain exceptions³ there appears to be a reluctance on the part of investigators to make positive commitments in the question. In a previous publication⁴ the junior author called attention to the probable implication of members of the genus *Proteus* in diarrheal diseases in man and the importance of collecting further evidence of etiologic relationships. The purpose of the present communication is to describe a small outbreak during which the predominating organism recovered was *Proteus mirabilis*.

FEATURES OF THE EPIDEMIC ‡

During the afternoon of December 26, 1944, a number of naval personnel became violently ill with gastroenteritis; all had eaten the noon meal at the mess hall in one of the barracks. Sliced baked ham was suspected as the vehicle of dissemination of the etiologic agent, since it was the article eaten by all the patients; it was placed on the menu

toward the end of the mess period after the original entree was exhausted, with the result that only 50 to 75 portions were served. The ham in question was of the ordinary whole smoked variety and had been baked on December 25 for use on that date. All hams were boned before baking; after this they were placed in galvanized pans to cool prior to slicing. After slicing, the meat was stored in a refrigerator in stainless steel pans until serving on the 25th; sliced ham not needed at this meal was kept in the refrigerator until it was required for use at the noon meal on the 26th. Fortunately, samples of the meat served at the suspected meal were still available for culturing when investigation of the outbreak was begun.

The onset of symptoms averaged 3 hours after ingestion of the suspected food. A total of 29 patients reported to the barracks dispensary and 19 of them were hospitalized; 17 of these were stretcher admissions but the other 2 were ambulatory. As soon as possible after reaching the hospital all patients were questioned individually concerning their symptoms, and specimens for culturing were obtained from 15 of them. All patients had severe nausea and vomiting. Nearly all of them gave a history of almost continual emesis in the acute stage which eventually resulted in bile-finged ejecta followed by watery fluid; blood was found in 2 specimens

‡ Taken in part from a report by Lieutenant H. F. Kruesburg (MC), USNR.

of vomitus. The numbers exhibiting other signs and symptoms were: (a) diarrhea, 18 of 19. The average number of stools per case in 9 patients was 8.9; 3 passed blood and 2 mucus; (b) abdominal cramps, 16 of 19; (c) fever, 3 of 19 with a maximum of 101° F., the other 16 had either normal or sub-normal temperatures, the lowest at admission being 92° F.; (d) evidence of peripheral collapse, 6 of 17 recorded. It was necessary to administer intravenous fluid in 11 of 18 cases recorded. Although the disease was severe, it was of short duration; the average length of illness for 18 patients was 40 hours.

BACTERIOLOGIC STUDIES

As mentioned above, a specimen of the ham involved was secured. Specimens were taken from 15 patients as follows: stool and rectal swab, 2; rectal swab and vomitus, 2; rectal swab only, 7; vomitus only, 4. Since it was ascertained that certain food handlers in the serving line during the suspected meal were suffering from concurrent upper respiratory infections, nasopharyngeal cultures were taken from 5 of these individuals; these were not obtained, however, until the 3rd day following the outbreak.

In view of the clinical and epidemiological aspects of the outbreak and previous experiences the laboratory procedures used recognized the possibility that one of two broad groups of bacterial species might have been the etiologic agent: (a) hemolytic, toxigenic strains of staphylococci or streptococci; or, (b) one of the groups of Gram-negative enteric bacilli, particularly of the genus *Proteus*. Cultural methods employed were as follows:

A. *Ham*.—Five grams selected to represent both the outer fatty and inner lean portions were triturated under sterile conditions with sand in a mortar until a smooth mixture was obtained. From the resulting suspension, 1.0 ml.

amounts of various dilutions were cultured in blood agar pour plates to represent in terms of the original ham 0.125, 0.005, 0.0005, and 0.00005 gm. respectively; in addition, a loopful each of undiluted suspension was streaked directly onto a blood agar plate and a plate of SS agar. To the remainder of the ham was added sterile tryptose phosphate broth from which, after suitable incubation, SS agar plates were streaked.

After 48 hours' incubation at 37° C., total bacterial counts were made from the blood agar plates. The average number of bacteria per gm. of original ham as calculated from the 3 highest dilutions was between 60,000 and 62,000; the counts at each dilution were satisfactorily consistent. Upon macroscopic study of the colonies and microscopic examination of a representative number it was found, however, that less than 20 per cent of the total growth was hemolytic and morphologically characteristic of *Staphylococcus aureus*, thus yielding an estimated count of fewer than 12,000 staphylococci per gm. of meat; growth of streptococci was completely insignificant. These findings were, therefore, markedly discrepant from the "hundreds of millions" of these organisms usually found in foods causing staphylococcal food poisoning.⁵

Essentially a pure culture of Gram-negative bacilli in large numbers was obtained on the SS agar plates streaked from the ham-tryptose-phosphate broth culture.

B. *Vomitus*.—The 6 specimens were each streaked onto blood agar plates and onto SS agar plates. Following suitable incubation and subsequent study no evidence of an etiologic relationship was found concerning a minimum number of what appeared to be beta-hemolytic streptococcal colonies that grew on the blood agar plates inoculated from 3 specimens.

From 3 of the 6 specimens streaked onto SS agar were obtained heavy growths of colonies of Gram-negative bacilli that were similar to those found in the ham-broth culture.

C. Fecal Material—Seven of 11 rectal swab specimens that were cultured on SS agar yielded large numbers of colonies of Gram-negative bacilli similar to those found in the ham-broth culture; there were very few colonies of other organisms. A stool specimen obtained from a patient from whom a rectal swab specimen was positive also yielded typical colonies on SS agar.

D. Throat Cultures—Nasopharyngeal, and in 1 case also peri-tonsillar, swab specimens were taken from 5 food handlers; these were cultured on blood agar plates in the usual manner. No growth of pigmented, hemolytic or otherwise significant colonies was obtained from 4 subjects. From both specimens taken from the other individual cultures of what appeared to be beta-hemolytic streptococcal colonies were obtained; further study, however, failed to reveal any etiologic relationship.

In all, 12 representative cultures of the Gram-negative bacillus obtained in predominance were selected for further study. The sources of these strains were as follows: ham, 1; rectal swab, 7; stool, 1; vomitus, 3. Only 9 patients are represented since in one instance both a stool and swab specimen were positive and in another the organism was recovered from both swab and vomitus specimens.

Biochemically, the 12 cultures were identical and were typically *Proteus mirabilis*. They produced acid and gas within 24 hours in glucose, xylose, and trehalose; acid and gas formation in sucrose was delayed for 2 to 4 days. The cultures actively hydrolyzed urea and produced large amounts of hydrogen sulfide within 24 hours; they were motile, they liquefied gelatin within 2

days and reduced trimethylamine oxide. The strains failed to ferment lactose, mannitol, maltose, rhamnose, dulcitol, arabinose, inositol, salicin, sorbitol, or adonitol during 14 days' incubation; all failed to utilize Koser's citrate and none produced indol.

SEROLOGIC STUDIES

Two of the strains were selected for immunizing rabbits; 1 (No. 527) was the culture isolated from ham and the other (No. 498) was from the stool specimen of a patient. Formalinized broth cultures of the organisms were too toxic to rabbits for immunization purposes. Antigens for inoculations were made by suspending the 18–24 hour growth on agar in physiologic saline containing 0.3–0.4 per cent formalin; previous passage of the cultures through semisolid agar⁶ insured a maximum of flagellar elements. The initial dosage was 0.2 ml. of the suspension diluted to contain approximately 1 billion organisms per ml.; 5 subsequent injections were given in amounts of 0.5, 1.0, 2.0, 2.0 and 2.0 ml., respectively. All inoculations were administered intravenously and the interval was either 4 or 5 days. The rabbits were bled from the heart on the 8th day after the last dose of vaccine.

Both sera were tested for O and H agglutinin titers against all 12 strains. The O and H antigens were prepared from smooth cultures by the methods employed for salmonellas.⁶ The O titers were significantly strong for all strains with both sera through a dilution of 1:80, indicating that the somatic antigens were similar if not identical. Essentially equally strong H reactions were obtained with both sera when tested in dilutions of 1:5,000, 1:10,000, and 1:20,000 against the 12 strains thus suggesting that the H antigens were also closely related if not identical.

In order to test further the identity

of the somatic and flagellar antigens, adsorptions of the 2 sera were made as follows: (a) serum homologous for the ham strain (No. 527) adsorbed with a stool strain (No. 498) and another portion adsorbed with a strain isolated from vomitus (No. 512); (b) serum homologous for the stool strain (No. 498) adsorbed with the ham strain (No. 527) and a second portion adsorbed with the vomitus strain (No. 512). The results of these adsorptions and subsequent agglutination tests are shown in Table 1.

demics of enterointoxication. It is possible that higher staphylococcal counts might have been obtained if additional specimens of the ham had been cultured; under the same conditions, however, larger numbers or Gram-negative bacilli might also have been found. It is somewhat unfortunate that it was not possible to conduct tests for enterotoxigenicity; such tests are frequently omitted when the bacterial counts are as low as those reported in this paper. Although no tests were done for the detection of a poisonous chemical agent,

TABLE 1
Agglutination of Pr. mirabilis Strains

Serum	Serum Adsorbed by Culture No.	Ham — No. 527		Stool — No. 498		Vomitus — No. 512	
		"O" *	"H" **	"O"	"H"	"O"	"H"
Stool No. 498	Unadsorbed	+	+	+	+	+	+
	512	—	—	—	—	—	—
	527	—	—	—	—	—	—
Ham No. 527	Unadsorbed	+	+	+	+	+	+
	498	—	—	—	—	—	—
	512	—	—	—	—	—	—

* + = Significant agglutination in 1:80 dilution or higher; — = no agglutination in any dilution down to 1:2½.

** + = Significant agglutination in dilutions through 1:20,000; — = no agglutination in any dilution down to 1:100.

The other 9 strains were tested with the two sera, unadsorbed and adsorbed, as shown above, with identical results. The evidence indicates, therefore, that the strains isolated from patients were all serologically identical with the strain isolated from the ham.

DISCUSSION

The failure, by the usual methods, to implicate members of the staphylococcal or streptococcal species in the outbreak does not necessarily exclude these organisms as possible causative agents. The number of staphylococci found per gm. of meat appears to be more nearly consistent with normal bacterial counts than with the markedly excessive numbers found when these organisms have been etiologically incriminated in epi-

the incubation period and, in part at least, the symptomatology are not consistent with such a diagnosis.

The demonstration of what appear to be identical strains of *Proteus mirabilis* in the suspected food and in vomitus and fecal specimens of 9 of the patients does not prove, but strongly suggests the etiologic relationship of this organism. The incubation period, symptoms, and convalescence are all consistent with this opinion in view of the report by English workers.³ It was not possible to conduct tests for the enterotoxigenic properties of the strains isolated, but broth cultures have been uniformly fatal in small doses when administered intravenously to rabbits. The short incubation period also suggests that a bacterial toxic substance

played an important part in the symptomatology. The fact that the organisms were recovered in large numbers from the feces of several patients may well point to a transient but definite infection of the intestinal mucosa. In a series of observations to be reported later, some supportive evidence will be presented concerning the probable part played by members of the genus *Proteus* in sporadic and epidemic cases of gastroenteritis.

SUMMARY AND CONCLUSIONS

Strains of *Proteus mirabilis* that were apparently identical biochemically and serologically were isolated from suspected ham and from 9 of 19 patients who became violently ill with gastroenteritis after eating the food. Attempts to demonstrate a causal relationship of

staphylococci or streptococci were unsuccessful. It is believed that the studies furnish strong circumstantial evidence of the probable etiologic relationship of *Proteus mirabilis*. Clinical, bacteriological, and serological observations are described briefly.

Dental Care in UNRRA Camps

Lt. Col. George A. Nevitt, Chief Dental Consultant at UNRRA's London Headquarters, recently announced that dental care is now available for 1,300,000 displaced persons in camps in Germany, Austria, and the Middle East. The basic treatments, consisting of extractions, fillings, treatments of diseases of the mouth, and replacement

of missing teeth, are given by displaced dentists in the camps. Their work is supervised by six UNRRA area dentists and the camp health experts.

UNRRA has provided 100 complete units of dentistry equipment in Greece; it has also provided six scholarships to Greek dentists for postgraduate work in the United States and Britain.

Public Support for Multiple County Health Departments

RICHARD F. BOYD, M.D., M.P.H., F.A.P.H.A.

Chief, Division of Local Health Administration, Illinois Department of Public Health, Springfield, Ill.

DURING the past several years there has been an ever increasing tendency for adjacent counties to pool their efforts and resources in the protection of their peoples against public health hazards by the formation of multiple county health departments. Dr. F. W. Kratz has called attention to the fact that in 1935 there was a total of 561 full-time health departments in the United States.¹ Of these, 41 were local district (multiple county) health departments. In 1942 the total number of full-time health departments had increased to 975, while local district (multiple county) health departments had increased to 187. Thus, in 1935, local district (multiple county) health departments represented 7.3 per cent of the full-time health departments in the United States, while in 1942 this percentage had increased to 19.2 per cent. Admittedly, some of the increase in the number of multiple county health departments during this period may be attributed to the fact that adjacent counties having full-time single county health departments were forced to share a health officer because of the shortage of personnel due to the world conflict. However, the writer is of the opinion that in many instances this may have proved to be a wholesome situation, since in the past, all too frequently, health officers were found to be serving small populations. This often represented a waste of public health manpower. The Subcommittee on Local

Health Units of the American Public Health Association proposes that one health officer with adequate training and experience should serve a population of not less than 50,000 persons, even with assistance on a part-time basis from local medical practitioners for certain public health programs.²

In order that multiple county health departments may be established it is necessary either that legislation exist permitting or requiring this procedure, or that at least there be no statutory contraindication to this arrangement. In Illinois we are fortunate in this respect. A statute commonly known as the Searcy-Clabaugh County Health Department Law was enacted in Illinois in 1943.³ This legislation permits any county or two or more adjacent counties to establish and maintain a full-time health department. If four or more counties wish to establish a multiple county health department, it is necessary that permission for this combination be obtained from the State Department of Public Health. Of the 26 states listed by Emerson as having laws relative to county or multiple county health departments, 22 appear to provide for the organization of multiple county health departments.⁴ It is noted that a considerable amount of the legislation relative to multiple county health departments was enacted only recently. This appears to indicate a wholesome trend.

The mere existence of legislation per-

mitting the establishment of multiple county health departments is, of course, only a first step. In order that multiple county health departments may be established, public interest and support are necessary. It is also realized that it is more difficult to arouse simultaneous interest and support in two or more counties in a proposal for the establishment of a multiple county health department than is the case when only one county is involved. In order that this necessary interest and support may be aroused and maintained, a number of factors must be considered in selecting counties for consolidation.

It would appear desirable that the public health problems of the counties involved be similar in character. This enables the attention of the populations involved to be focused upon similar public health situations. It is also considered important that the folkways and mores of the people of the counties involved be the same. In general, the habits and customs of peoples in contiguous counties are the same. There are, however, exceptions, and when such situations come to light, a rearrangement of plans for consolidation may frequently avoid difficulty. It is also believed that the consolidation of counties which are rather similar in regard to per capita wealth and population is desirable. When an attempt is made to promote the consolidation of a rich and a poor county, or a populous and a sparsely populated county, the people of the rich or populous county are often fearful that they will have to assume the burden of "a poor relative." On the other hand, the people of the poor or sparsely populated county are fearful that the lion's share of services of the health department will be received by the rich or populous county. Truly enough, this situation can be overcome by careful explanation and the institution of certain safeguards, but can often be avoided entirely by carefully choos-

ing the counties for a proposed multiple county health department.

One usually finds also that a county which is essentially industrial does not consolidate smoothly with a county which is chiefly agricultural in nature. The public health problems of counties of these types usually differ rather markedly, and the people of the latter county tend to be more conservative than those of the former. A factor which is of a very practical nature, and one which may at first be overlooked, is that of travel facilities between the two counties, and especially between the two county seats. This is a situation which is immediately recognized by local groups but is all too frequently neglected by public health administrators who attempt to lay plans for the consolidation of health services from their offices in the state health department.

Much of the foregoing may appear irrelevant to the subject of public support for multiple county health Departments. However, I believe that many public health administrators who have had practical experience with these problems will recognize the validity of these statements.

To come to the subject for discussion, the person or persons who are seeking public support for a proposed multiple county health department will recognize that this support must come from several sources. The proposal must have the support of the governing bodies of the counties involved, since in many cases they will be relinquishing certain powers and duties, and these groups are made up of the persons who will make possible an appropriation for the financial support of the health department.

It should also be pointed out that, although powers and duties are often lost by individuals at the time of the establishment of a multiple county health department, the governing bodies

of the individual counties frequently acquire additional strengths at this time. For example, in Illinois the establishment of a multiple county health department results in the automatic abolition of all Township Boards of Health, thus decreasing the powers and duties of the individual supervisors of townships. However, the County Boards of Supervisors are enabled, after the establishment of a full-time health department, to adopt rules and regulations relating to public health matters, a power which they lacked prior to the establishment of the full-time health department.

The interest and support of professional groups will need to be aroused, since the attitude of the members of the local medical and dental professions will carry much weight with the county officials and the public. The active coöperation of these organized groups is also necessary for the successful operation of the health department after establishment. Of course, the interest and support of the citizens of the counties involved must be obtained. The attitude of the public will exert much influence on the governing bodies of the county and, in some instances, as will usually be the case in Illinois, a favorable vote by the electorate in a referendum is necessary in order that a multiple county health department may be established.

The immediate reaction of the members of the governing bodies of counties for which consolidation is proposed will usually depend upon their experience in the past with the officials of the county or counties with which combination is suggested. If this relationship has been a pleasant one, the proposal is apt to be favorably received from the outset. On the other hand, if the relationship has been unpleasant, a great deal of careful explanation of the provision safeguarding the interests of the individual counties will be necessary. These explana-

tions, supported by manifest public approval, will often prove effective in obtaining the support of the county officials to the extent of securing the appointment of a group of individuals from each governing body to serve on a joint committee to give further consideration to the proposal. Meetings of such a committee make possible a thorough discussion of the proposition and joint consideration of the interests and problems involved. These meetings also make it possible for the officials of the counties to develop acquaintanceships which will be helpful in maintaining the support of the governing bodies for the health department after establishment.

Fortunate is the public health administrator who finds that the professional societies of the counties suggested for consolidation either exist as a joint county society or have frequent joint meetings. If such is the case the development of the support of these groups is usually greatly facilitated. At any rate, it is desirable that in this instance also joint committees be appointed from the professional societies to give consideration to the proposal and discuss the principles involved. Out of such committee meetings will usually come the support and coöperation desired.

In Illinois we are very fortunate in having as an effective tool for the development of public interest and support for local health services a Statewide Public Health Committee. This committee was formed in 1942 because of a recommendation growing out of a survey of the Illinois Department of Public Health by the Committee on Administrative Practice of the American Public Health Association.⁵ The Statewide Public Health Committee consists of influential persons throughout Illinois having a known interest in public health matters. It was established for the purpose of arousing public interest in a statute permitting coun-

ties to establish and maintain full-time local health departments, and after or coincident with the enactment of this legislation to develop public interest in each county in good local health services. The legislation mentioned above having been obtained in 1943, the Statewide Public Health Committee is now devoting the major portion of its efforts toward the implementation of the plan which has been developed by the Illinois Department of Public Health for the complete coverage of the state with county and multiple county health departments.⁶

County components of the Statewide Public Health Committee have been organized in a number of Illinois counties. When interest is found in the development of a multiple county health department, the county components of the Statewide Public Health Committee, if existing already, are swung into action. If such committees do not exist there will usually be found in each of the counties members of the Statewide Public Health Committee who can be used as nuclei for the organization of such committees. From these groups a joint committee is appointed to discuss the suggestion for the development of a multiple county health department and study the local health problems of the area. After issues have been clarified through this study, various existing organizations in each county are approached and acquainted with the proposal and their active coöperation and support are solicited. By this means a substantial cross-section of the opinion of both counties is reached and a favorable attitude toward the proposal is engendered.

The discussion heretofore has related principally to the development of coöperation and support of various organizations and groups to the end that a multiple county health department be established. A continuation of this public support after establishment is,

of course, necessary if the health department is to operate successfully. In order to assure the continuation of this interest, the joint committee set up prior to the establishment of the health department should be perpetuated. The joint committee of the governing bodies of the counties will find it necessary from time to time to discuss the responsibilities of each body in regard to the financing of the health department. These and other problems will act as stimuli to keep the interest of this group alive. The joint committees of the professional groups could logically grow into advisory committees to the health department. It is also usually considered desirable procedure to permit the professional groups to make nominations for the appointment of the professional members of the multiple county Board of Health which, under the County Health Law in Illinois, consists of three persons from each county, one from each county being a physician and one member of the multiple county Board of Health being a dentist. Responsibilities of this type which fall upon the professional groups will aid in maintaining their interest. The joint committee of the County Public Health Committees could in similar manner become the lay advisory committee to the health department. This committee can serve to protect the health department by vigorously supporting the appointment of a multiple county Board of Health composed of competent and interested persons, by promoting the appointment of a well trained staff for the health department, and supporting the health officer in obtaining an adequate budget for the department. Similarly, the county public health committees from which the joint committee was appointed should continue to function, since they will need to support the lay advisory committee in its endeavors and, having studied the public health situations of their respec-

tive counties, can interpret to the health officer local public health problems which are in need of solution.

In conclusion, public support of multiple county health departments depends upon the following factors:

1. Adequate legislation.
2. Care in the selection of counties for consolidation
3. Interest and coöperation of governing bodies
4. Interest and coöperation of professional groups
5. Strong lay public health committees

6. A populace which has been made conscious of their public health problems

State Geriatrics Institute Planned for May

A one-day geriatrics institute sponsored by the Indiana University School of Medicine and the Indiana State Board of Health will be held in the auditorium of the Indiana University School of Medicine May 22. The purpose of the institute is to study the process of aging, the problems of the aged, and the more common diseases and disabilities associated with aging. In attendance will be physicians interested in geriatrics, educators, dentists, nurses, social workers, representatives of industry and labor and, in fact, all who may have an interest in the medical, social, and economic problems connected with the rapidly increasing age of our population.

The forenoon session of the institute will be devoted to a discussion of Health Guidance in Maturity, Mental Hygiene and Geriatrics, with a symposium on diseases of advancing years including cardiovascularrenal diseases, arthritis, cancer, eye and ear diseases, and hormone therapy. Dr. W. D. Gatch, Dean of Indiana University School of Medicine, will preside at the forenoon session.

Dr. L. E. Burney, State Health Commissioner, will preside at the afternoon session. The program will be devoted to an address on geriatric medicine by Dr. E. J. Stieglitz, Washington, D. C., Consultant in Gerontology to the National Institute of Health, and author of a book on geriatric medicine. As a further part of the afternoon program the subject, Aging as an Industrial Health Problem, will be discussed by a representative of labor, a representative of management and an industrial physician.

A public meeting in the evening to be addressed by a speaker of national reputation and experience is planned as a conclusion to the institute. All the facilities of the Indiana University School of Medicine and of the State Board of Health will be devoted to making this institute a success and in creating a widespread interest, both professional and public, in the purpose of the institute.

The program will begin at 9 A.M., continue throughout the day, and close with the evening meeting for the general public.

Tularemia

A Report on 40 Cases in Alberta, Canada, 1931-1944

MALCOLM R. BOW, M.D., D.P.H., F.A.P.H.A., AND
JOHN H. BROWN, M.Sc.

*Deputy Minister of Health, and Public Health Entomologist, Department of
Public Health, Edmonton, Alberta, Canada*

TULAREMIA was first recorded in Alberta in 1932 when Shaw and Jamieson⁵ reported a case that occurred at Tofield in 1931. The next record was by Wright⁶ in 1935 when he reported two cases in the Athabasca district. In 1939 Brown³ reported a tick-transmitted case, and in 1943 Bow and Brown² reported two cases at

Whitla. In 1945 Bell¹ reported a case contracted by a packing-plant employee.

INVESTIGATIONS

On account of the fact that tularemia simulates so many other diseases it is difficult to diagnose clinically. In Alberta prior to 1934 blood tests were carried out only on those cases which

the attending physician suspected as being tularemia. However, in that year the Provincial Laboratory began to include *Pasteurella tularensis* as an antigen in routine agglutination tests for typhoid and related organisms. By this means a small number of cases of tularemia were found that might otherwise have been missed.

Some of the blood sera examined agglutinated *P. tularensis* to a low titer only and, as the patients concerned did not present clinical evidence of tularemia, it was considered that the positive reaction might have been due to an old infection or some other cause. Such deduction follows the theorizing of Francis and other eminent workers in the field of tularemia. However, these routine tests proved of great assistance in the diagnosis of some obscure cases.

The following report is based on material collected from physicians and hospitals, and supplemented by laboratory findings. The cases are divided into groups: Group I: Accepted Cases; Group II: Probable Cases.

GROUP I

Accepted Cases

Cases were accepted as proven when

there were a clinical picture of tularemia; a history of exposure to a source known to be capable of transmitting tularemia; and satisfactory laboratory findings.

Since 1931 a total of 35 such cases, of which 4 were fatal, have occurred. They are recorded in Table 1.

Table 1 contains considerable information that is worthy of examination. Therefore, the table will be broken down for a detailed analysis of its various parts.

In 1934, which marked the inception of the routine laboratory tests, 8 cases were located. From then until 1940 only 4 cases were reported. In 1940 6 cases, in 1941 5 cases, in 1942 6 cases, in 1943 2 cases, and 1944 3 cases, were recorded. There is no indication in

TABLE 2

Number of Cases per Year

Year	Cases
1931.....	1
1934.....	8
1935.....	1
1936.....	2
1939.....	1
1940.....	6
1941.....	5
1942.....	6

TABLE 3

Monthly Cases with Contacts

Contact	January	February	March	April	May	June	July	August	September	October	November	December	Total
Rabbits	1	5	21
Ground squirrels	1	1	2
Cats	1 ¹	3
Ticks	1 ²	2	1	..	1
Grouse	1 ¹	1
Mink	1
Sheep	1 ²	1
Swine	1	1
Skunk	..	1	1	..	1	..	1	1	4
Unknown
Totals	..	1	..	2	4	7	5	5	3	6	3	1	37

¹ Both cat and mink involved as probable source in the one case.

² Both ticks and sheep involved as a source of infection as the patient had been skinning sheep dead from tularemia, and had also been bitten by infected ticks (Gwatkin, et al.⁴).

Table 2 that human tularemia in Alberta follows a cyclic pattern.

It is interesting to note that of the 35 cases, 26 occurred during the period June to October, inclusive. As tularemia is a disease that is mainly contracted through contact, such a distribution indicates that epidemiological studies might be productive of information of value.

The fact that only 21 of the cases were traced to contact with rabbits indicates that, although rabbits are the main source of infection, the sources, and potential sources, of tularemia are many and varied. There is a definite seasonal relationship of cases due to contact with rabbits, with all of the cases occurring during the period May to November, inclusive.

As the spotted fever tick is only active during the spring and early summer, seasonal human cases due to it are easily explained.

Tularemia infection in ground squirrels has been reported from three widely separated areas in Alberta. As these animals are active only during the warm seasons, it is natural to expect that they would be recorded as a source of human infection during the summer.

A SUMMARIZATION BY YEARS OF ACCEPTED CASES

1931

1. P.B., male, age 53; Tofield
Hospitalized—Nov. 6 to Nov. 23
Agglutination titer—1-5,000
Contact—Handling rabbits
Result—Recovered
Remarks—Pleural fluid inoculated into guinea pig produced *P. tularensis* infection. Organism isolated in pure culture from infected guinea pigs. (Reported: Shaw & Jamieson⁵)

1934

1. W.I., male; age 55; Berrymore
Hospitalized—July 7 to Aug. 20
Agglutination titer—1-800, Aug. 7, 1934
1-100, Dec. 3, 1934
Contact—Skinning rabbits
Result—Recovered

Remarks—Infection through finger prick.
Painful left axilla and general body pains

2. Mrs. W.S., age 44; Prosperity
Hospitalized—Aug. 15, 1934
Agglutination titer—1-200, Aug. 20
Contact—Skinning rabbits on Sept. 30, 1933 to feed dogs
Result—Recovered
Remarks—(Reported by Wright⁶)
3. O.S., male, age 48; Wabamum
Hospitalized—Oct. 7 to Oct. 20
Agglutination titer—1-800, Aug. 22, 1934
Contact—Skinning rabbits
Result—Recovered
Remarks—Scratch on left hand "festered."
Soreness and palpable gland in axilla
4. R.B., male, age 22; Gainford
Hospitalized—Oct. 19 to Dec. 31
Agglutination titer—1-320, Feb. 22, 1935
Contact—Handling rabbits
Result—Recovered
Remarks—"He felt well as usual until May, 1934, when he developed what was considered bronchial pneumonia. He was sick for two weeks, lost 51 lbs., had a high fever, and was, I believe, x-rayed at that time. He felt well from the middle of August till September, when he developed severe chill and pain in the region of the bladder and had difficulty in micturition. Temperature 99 to 101° for two weeks, with some night sweats. About October 1, 1934, he developed a cough.
On discharge from the Sanatorium, December 31, 1934, it was considered that this patient had a nontuberculous pneumonia involving the right upper chest and that he had almost completely recovered.
Subsequent to his discharge from the Sanatorium, it came to the attention of the attending physician that this young man had been handling rabbits to some extent. A specimen of blood submitted to the Provincial Laboratory, gave the usual findings for tularemia"
5. Mrs. J.P., age 32; Edmonton
Hospitalized—Nov. 2 to Nov. 28
Agglutination titer—1-800, Nov. 6, 1934
Contact—Cleaning grouse
Result—Recovered
Remarks—Infection of finger followed by enlarged axillary glands
6. F.W., male age 16; Perryvale
Hospitalized—Nov. 26 to Nov. 30
Agglutination titer—1-1,600, Dec. 3, 1934
Contact—Skinning rabbits
Result—Recovered

Remarks—Pus under fingernail of right hand, and a small lump in right axillary space. (Reported by Wright⁶)

Contact—Tick bite

Result—Recovered

Remarks—Tick bites on scrotum and chest.

Clinical diagnosis—typhoidal tularemia

7. Mrs. B., female, age 60; Edmonton

Hospitalized—(no)

Agglutination titer—1-800, Dec. 5, 1934

Contact—Skinning rabbits

Result—Recovered

Remarks—She received a scratch from a bone sliver while dressing a rabbit. Lymphangitis resulted, followed by pneumonia

8. H.F., male, age 31; Jasper

Hospitalized—Oct. 12 to Nov. 5

Contact—Bite of cat

Result—Recovered

Remarks—Bite on thumb

Re-hospitalized—Dec. 3, 1934 to Jan. 3, 1935

Agglutination titer—1-1,600, Dec. 7, 1934

Result—Recovered

Remarks—Swelling appeared in axilla Nov. 15 and was very painful, also painful swelling on arm

1935

1. Mrs. P., female, age 40; Winterburn

Not hospitalized

Agglutination titer—1-1,600, June 22, 1935

Contact—Rabbits

Result—Recovered

Remarks—Infection in hand and arm

1936

1. H.D., male, age 16; St. Paul

Hospitalized—July 19 to Aug. 3

Agglutination titer—1-1,600, Aug. 11, 1936

Contact—Ground squirrels

Result—Recovered

Remarks—Infection through cut on left hand while skinning ground squirrels

2. D.H., male, age unknown; Taber

Not hospitalized

Agglutination titer—1-1,600, Dec. 9

Contact—Not known

Result—Recovered

Remarks—Glandular tularemia involving the axillary and mediastinal glands

1939

1. T.M., male, age 30; Walsh

Hospitalized—May 11 to July 2

Agglutination titer—1-100—May 25

1-400—June 1

1-200—June 22

1-200—June 29

1-100—Aug. 4

1-100—Sept. 18

1940

1. Mrs. M.L., female, age unknown; Grimshaw

Hospitalized—May 21 to June 7

Agglutination titer—1-6,400, June 1, 1940

Contact—Rabbits

Result—Recovered

Remarks—Cut hand while skinning rabbits

2. Mrs. W.M., female, age 30; Seven Person's Coulee (Whitla)

Hospitalized—June 7 to July 23

Agglutination titer—1- 200—June 19

1-1,600—June 22

1-1,600—June 24

1- 800—Sept. 3

1- 400—Nov. 7

Contact—Tick bite

Result—Recovered

Remarks—Tick bite on inner part of left leg

Clinical diagnosis—Typhoidal tularemia

3. L.Y., male, age unknown; Winterburn

Hospitalized—June

Agglutination titer—1- 200—June 18

1-1,600—June 20

1-6,400—June 24

Contact—Rabbits

Result—Died

Remarks—Organism isolated from ulcer, June 25, by guinea pig inoculation

4. F.R., male, age unknown; Grimshaw

Not hospitalized

Agglutination titer—1-6,400, July 17, 1940

Contact—Rabbits

Result—Recovered

Remarks—Bitten on hand by rabbit

5. Miss F. L'H., female, age unknown; Grimshaw

Hospitalized—July 31 to Aug. 16

Agglutination titer—1-3,200, Sept. 21, 1940

Contact—No known contact with rabbits.

Possibility of having eaten chicken or some animal which might have ingested infected rabbits

Result—Recovered

Remarks—No known contact with rabbits. Very sore throat and massive glands in neck.

6. Miss N.S., female, age unknown; Vegreville

Hospitalized—Oct. 10 to Nov. 15

Agglutination titer—1-3,200, Oct. 26, 1940

Contact—Rabbits

Result—Recovered

1941

1. Mrs. H.LaR., female, age 34; Prairie Echo
Hospitalized—July 8 to Aug. 4
Agglutination titer—1-400, July 10, 1941
Contact—Rabbits
Result—Recovered
Remarks—General malaise, fever, headache
and symptoms of basal pleurisy—right
base
2. Miss L., female, age 17; Prairie Echo
Hospitalized—Aug. 3 to Aug. 30
Agglutination titer—1-1,600, Aug. 5, 1941
Contact—Rabbit
Result—Recovered
Remarks—General malaise, headache, and
pyrexia
3. W.B., male, age unknown; Notikiwin
Hospitalized—Aug. 6 to Oct. 17
Agglutination titer—1-800, Aug. 13, 1941
Contact—Rabbits
Result—Recovered.
Remarks—Caught rabbits, skinned and fed
them to pigs
Re-hospitalized—Oct. 18 to Nov. 19
Agglutination titer—1-400, Oct. 20, 1941
Contact—Rabbits
Result—Recovered
Remarks—Sputum injected into guinea pig
October 20, failed to infect
4. J.W.G., male, age unknown; Macleod
Hospitalized—Sept. 10 to Dec. 20
Agglutination titer—1-12,800, Sept. 29, 1941
Contact—Rabbits
Result—Recovered
Remarks—Skinning rabbits to feed dogs
5. T.S., male, age 62; Pibroch
Hospitalized—Nov. 22 to Dec. 17
Agglutination titer—1- 800—Nov. 25
1-51,600—Dec. 15
Contact—Unknown
Result—Recovered
Remarks—Final diagnosis was pleurisy.
Sputum injected into guinea pig Nov. 29
produced death of the pig with typical
lesions of *Pasteurella tularensis*

1942

1. M.L., male, age 49; Whitla (Seven Person's
Coulee)
Hospitalized—April 30 to May 22
Agglutination titer—1-400—May 26
1-400—May 30
Contacts—Tick bite and infected sheep
Result—Recovered
Remarks—Pleural fluid injected in guinea
pig on Aug. 4 and *P. tularensis* isolated.

This man suffered tick bites and also
handled *P. tularensis* infected sheep

2. E.A., male, age 58; Grimshaw
Hospitalized—June 15 to July 11
Agglutination titer—negative—June 15
1- 200—June 24
1-3,200—July 4
Contact—Rabbits
Result—Recovered
Remarks—Guinea pig inoculated with pleu-
ral fluid on July 4 developed typical
lesions of *P. tularensis*
3. N.P., male, age 14; Lac la Biche
Hospitalization—(no)
Agglutination titer—negative—July 9
Contact—Rabbits
Result—Recovered
Remarks—Abscesses in both axillae
Re-hospitalized—Sept. 3 to Sept. 16
Agglutination titer—1-400, Sept. 8, 1942
Contact—Rabbits
Result—Recovered
Remarks—Handling rabbits
4. H.M., male, age unknown; Radway
Hospitalized—Aug. 24 to Aug. 29
Contact—Ground squirrels and rabbits
Results—Recovered
Remarks—Ulcer on toe and abscess on
thigh, guinea pig inoculated Aug. 28, died
Sept. 2, *P. tularensis* isolated
Re-hospitalized—Sept. 7 to Sept. 11
Agglutination titer—1-6,400, Sept. 8, 1942
Contact—Ground squirrels and rabbits
Result—Recovered
Remarks—(same as above)
5. J.W., male, age 59; Anton Lake
Hospitalized—Sept. 24 to Oct. 11
Agglutination titer—1- 3,200—Oct. 3
1-12,800—Oct. 7
Contact—Unknown
Result—Died, Oct. 11, 1942
Remarks—M2878/42 Sputum collected on
Oct. 8 inoculated into guinea pig Oct. 8,
1942, which showed typical lesions of
Past. tularensis

M2906/42 Citrated blood collected Oct. 9,
1942, and inoculated into guinea pig on
Oct. 10, 1942; this guinea pig was killed
when apparently ill on Oct. 15, 1942. No
gross or microscopic lesions of tularemia
were found. Material from the liver of
this guinea pig was inoculated into a
second guinea pig which died on Oct. 25
and showed typical lesions of tularemia
in spleen, glands, and liver

P.M./40/42 Autopsy Oct. 11, 1942. Speci-

mens from pleural fluid, spleen, spleen abscess, lung and abscess in axilla when inoculated on Oct. 14, 1942, into five guinea pigs respectively caused *Past. tularensis* infection. All showed typical lesions in 4 to 7 days. Material from liver failed to cause infection. Culture of *Past. tularensis* was obtained from guinea pig inoculated with pleural fluid. Cultures made from pleural fluid, spleen, spleen abscess, liver, abscess in axilla were all negative on blood agar and cystine agar. Culture from left lung; 1. Non-hemolytic streptococci. 2. Freidlander's bacillus. 3. *Staphylococcus pyogenes aureus* -

6. E.B., male, age 11; Ft. Assiniboine
Hospitalized—Oct. 20 to Nov. 1
Agglutination titer—1-400, Dec. 1, 1942
Contact—Rabbits
Result—Recovered
Remarks—None

1943

1. M.K., male, age 36; Edmonton
Hospitalized—May 28 to July 10
Agglutination titer—negative—June 2
1-1,600—June 10, 1943
Contact—Scratch on finger from pig's tooth while working at packing plant
Result—Recovered
Remarks—Pleural fluid inoculated into guinea pig on June 15. Lesions in guinea pig typical of *Past. tularensis*. (Reported by Bell¹)
2. G.O., male, age 40; Cold Lake
Hospitalized—July 14 to July 24
Agglutination titer—Negative—July 7
1-100—July 12
1-800—July 14
Contact—Mink bite on little finger of left hand on June 22. Cat bite at same site on June 28.
Result—Died, July 24, 1943
Remarks—Thirty-six hours after the cat bite, patient became dizzy, ill and feverish. Guinea pig inoculated on July 28 with material collected at post-mortem from spleen. Lesion in the guinea pig typical of *Past. tularensis*

1944

1. G.H., male, age 51; Barrhead
Hospitalized 5 weeks, February-March
Agglutination titer—1-200—Mar. 22
1-100—Oct. 26
Contact—Cut finger while skinning a skunk
Result—Recovered

Remarks—Clinical diagnosis glandular type of tularemia. Lost 40 lbs. in 5 weeks in hospital

Treatment—Drainage of lymph sulfathiazole

2. F.S., male, age 14; Lake Isle
Hospitalized—June 10 to Aug. 23
Agglutination titer—1-100—June 17
1-1,600—June 22
1-3,200—July 12

Contact—Rabbits

Result—Died, August 23, 1944

Remarks—Primary lesion in conjunctival sac of right eye. On June 15, 1944, guinea pig M3701/44 inoculated with material from right eye. The pig died in 6 days and showed typical lesions of *Past. tularensis* in liver, spleen and lymph nodes.

M3810/44 . . . June 19, 1944. Cerebral spinal fluid yielded pure culture of *Past. tularensis*. Two guinea pigs inoculated on June 19 were killed on June 23 when very ill; both showed typical lesions of *Past. tularensis*, in spleen, liver and lymph nodes.

M4370/44 . . . July 19, 1944. Guinea pig inoculated with cerebral spinal fluid—negative.

P.M. 25/44 . . . August 23, 1944. Guinea pigs inoculated from autopsy material collected from pleura, heart blood, and brain were all healthy at the end of 10 days and were negative for *Past. tularensis* infection. The pig inoculated with material from the spleen died in 5 days with typical lesions of *Past. tularensis*. Cultures from lung tissue and pleura yielded hemolytic streptococci.

3. Mrs. A.D., female, age unknown; Nakamun
Hospitalized—June 22 to July 21
Agglutination titer—1-400, June 23, 1944
Contact—Rabbit through cut on finger
Result—Recovered

Remarks—Guinea pig inoculated June 24 with pus from axilla and thumb, killed when moribund June 28 and showed typical lesions of *Past. tularensis*

GROUP II

Probable Cases

Cases diagnosed as tularemia in which the agglutination tests were positive, but in which no adequate, detailed clinical history nor evidence of

TABLE 4
Probable Cases by Years

Year	Month	Name	Sex	Age	Location	Agglutination Titer	Contact	Result
1941	September	L.J.	M	?	Athabasca	1-3,200	Unknown	Recovered
	November	H.L.	M	44	Lac la Biche	1- 800	Unknown	Recovered
	November	D.F.	M	?	Berwyn	1-1,600	Unknown	Recovered
1942	September	R.V.	M	?	Grassland	1- 400	Unknown	Recovered
1944	May	G.L.	M	22	Mulhurst	1- 400	Unknown	Recovered

contact with a likely source of infection by *P. tularensis* are available.

Five cases in this category have been reported since 1941. These cases are listed in Table 5.

TABLE 5
Summary of Cases

1941

1. L.J., male, age unknown; Athabasca
Not hospitalized
Agglutination titer—1-3,200, Sept. 3
Contact—Not known
Result—Recovered
Remarks—The blood serum of this patient also agglutinated *B. abortus* 1-3,200. The attending physician regarded this as a case of tularemia

2. H.L., male, age 44; Lac la Biche
Hospitalized—Oct. 18 to Nov. 7
Agglutination titer—1-800, Oct. 24
Contact—Not known
Result—Recovered
Remarks—Had suppurative axillary adenitis on admission

3. D.F., male, age unknown; Berwyn
Not hospitalized
Agglutination titer—1-1,600, Nov. 22
Contact—Not known
Result—Recovered
Remarks—Diagnosed as tularemia

1942

1. R.V., male, age unknown; Grassland
Hospitalized—No
Agglutination titer—1-400, Sept. 3
Contact—Not known

Result—Recovered

Remarks—None

1944

1. G.L., male, age 22; Mulhurst

Not hospitalized

Agglutination titer—1-200, May 25

1-400, May 28

1-400, May 29

1-400 June 7

Contact—Handled muskrats but no history of bites

Result—Recovered

Remarks—No evidence of ulcer. Possible glandular type of tularemia with entrance of organisms through the skin.

ACKNOWLEDGMENTS—The authors wish to acknowledge the assistance received from Dr. R. M. Shaw, Provincial Bacteriologist and Professor of Bacteriology, University of Alberta. Dr. Shaw supplied the laboratory data, and gave much constructive criticism during the preparation of this paper. Acknowledgment is also made of the assistance received from physicians and hospitals, generally.

Wartime Changes in the Age Distribution of Females Infected with Syphilis

Their Effects on Epidemiologic Procedures and Program Planning

J. R. HELLER, JR., M.D.

Medical Director, Chief, Division of Venereal Diseases, U. S. Public Health Service, Bethesda, Md.

SINCE 1940 there has been much speculation concerning possible changes in the age at which new infections of venereal disease occur. It has been the general impression that the teen age group is forming an increasing proportion of the problem. This point has been brought out on a number of occasions in addresses on social problems and police and welfare work,¹⁻⁴ usually based on conclusions drawn from personal experience without statistical analysis. Several more objective studies have been made^{5,6} in which such a trend toward the teen ages has been deduced from the fact that a lower median age of infection can be demonstrated in specific areas studied. Beyond these studies little statistical evidence has been presented to show either the occurrence or non-occurrence of a shift in the age at which infections occur.

By means of the services of the regional and state tabulating units throughout the United States, it has been possible to obtain a large body of data tabulated by single years of age and by race and sex concerning patients admitted to public clinics for early syphilis. It is the purpose of the present study to analyze these data with respect to any changes which may have oc-

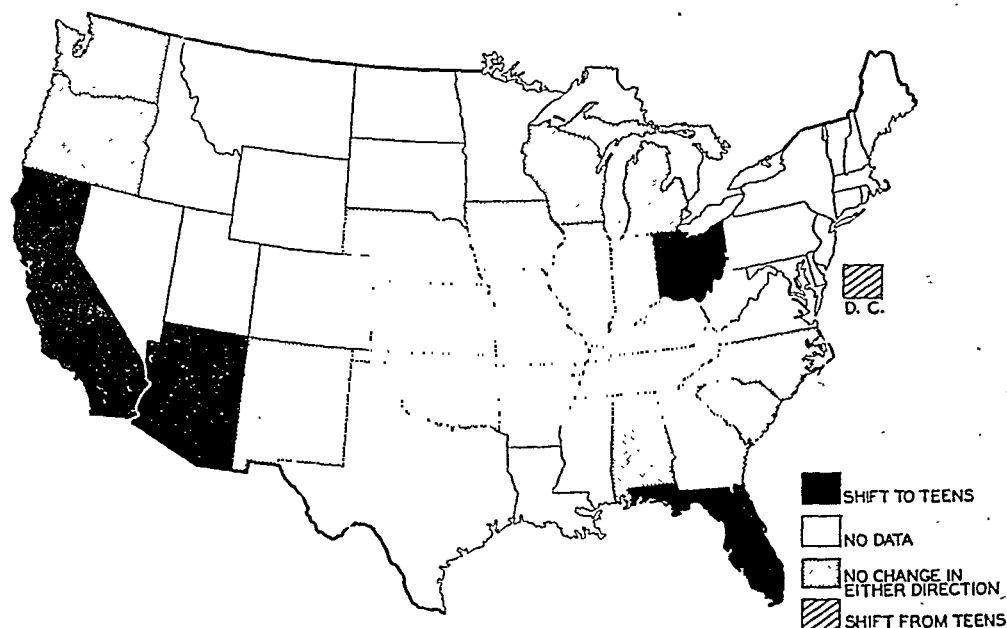

curred in the age at which syphilis is acquired.

Data were available covering the years 1941 through 1944 for the following states: Ohio, Indiana, Illinois, Michigan, Wisconsin, Iowa, Missouri, Nebraska, Kansas, North Carolina, South Carolina, Florida, Alabama, Oklahoma, New Mexico, Arizona, Washington, Oregon, and California, and for the cities St. Louis, Chicago, New York, and the District of Columbia.

The analysis was limited to females since male admissions to public clinics have been directly affected to such a large extent by the changing Selective Service Regulations.

The usual method of analysis of age trends, namely the investigation of differences between median ages, was not used since a change in age distribution is reflected in the median only when such a change occurs between age years higher than and lower than the median. For instance, a shift from the early twenties in one year to the teens in the next year would not be reflected in the median if this average happened to fall in the middle twenties for both years. Instead it was decided the data should be considered as a whole, and the per cent which the admissions at

CHART 1—Changes in Age Distribution of White Females Infected with Syphilis Admitted to Public Clinics, 1941–1942

each year of age was of the total admissions was compared from one year to the next. Chi square tests were calculated for the paired individual years of age to test the significance of the observed changes.*

Charts 1 through 6 show for each state the changes that have occurred from 1941 to 1944 in the age distribution of females acquiring syphilis.

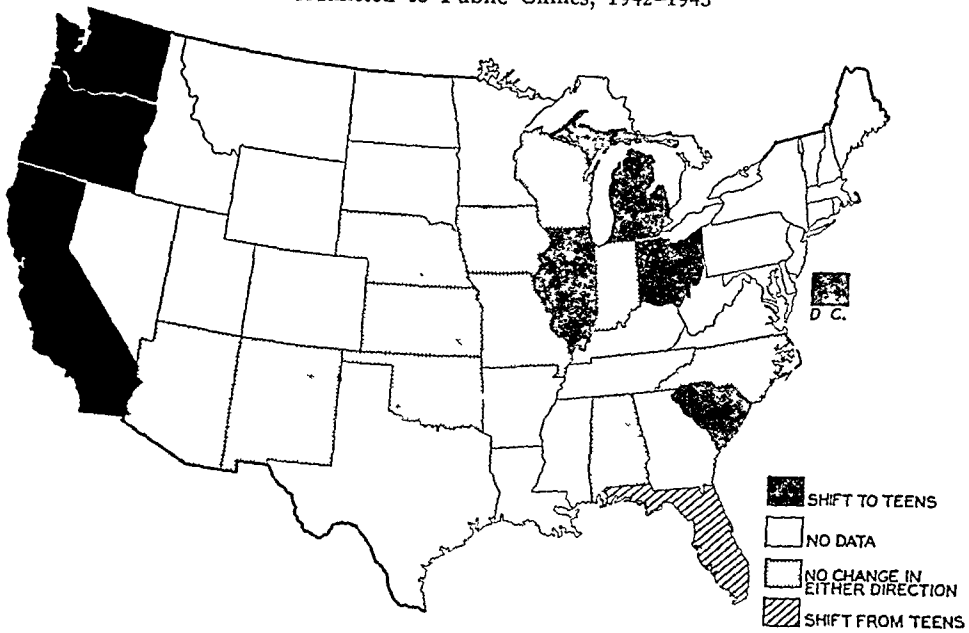

The study reveals that a shift into the teen ages has by no means been nation-wide; nor has it been constant from one year to another. Furthermore, the areas affected have not been the same for whites and Negroes. Many states show no shift of any kind, and some states show a shift away from the teens. Among the white females, California was the only state which exhibited an increasing tendency toward teen age infections through the whole study period. On the other hand, Florida shifted to the teens from 1941 to 1942; shifted back to the older ages

between 1942 and 1943, and showed no change from 1943 to 1944. Among Negro females, Florida and South Carolina showed a constant trend toward the teen ages; whereas Missouri was different in every period. Certainly for both races, fewer states experienced a shift to the teens than experienced no shift or a shift to the older ages.

Among the few large cities studied, there was also no particular consistency in the results obtained. No change of any kind was noted in St. Louis in any year for either race. In the District of Columbia among white females, there was a shift to the older ages from 1941 to 1942, to the teens from 1942 to 1943, with no change occurring between 1943 and 1944. Among colored females, on the other hand, there was a shift to the teens in the first and last paired years with no change shown between 1942 and 1943. No change occurred among white females in New York City, but there was a shift to the teens among colored females from 1942 to 1943. Among white females in Chicago, no change was noted from 1942 to 1943

* The method of analysis is described on page 510 of this issue.

CHART 2—Changes in Age Distribution of White Females Infected with Syphilis Admitted to Public Clinics, 1942–1943

or from 1943 to 1944. There was a significant difference between 1941 and 1942 but no particular pattern could be found. There was a significant shift to the teens between 1941 and 1942 and between 1942 and 1943 among colored females in Chicago; but

they shifted back again to the older years significantly in 1943 and 1944.

The sample on which the foregoing analysis was based is fairly representative of the country as a whole; including large parts of the midwest, far west, and southwest, and four large cities. When

CHART 3—Changes in Age Distribution of White Females Infected with Syphilis Admitted to Public Clinics, 1943–1944

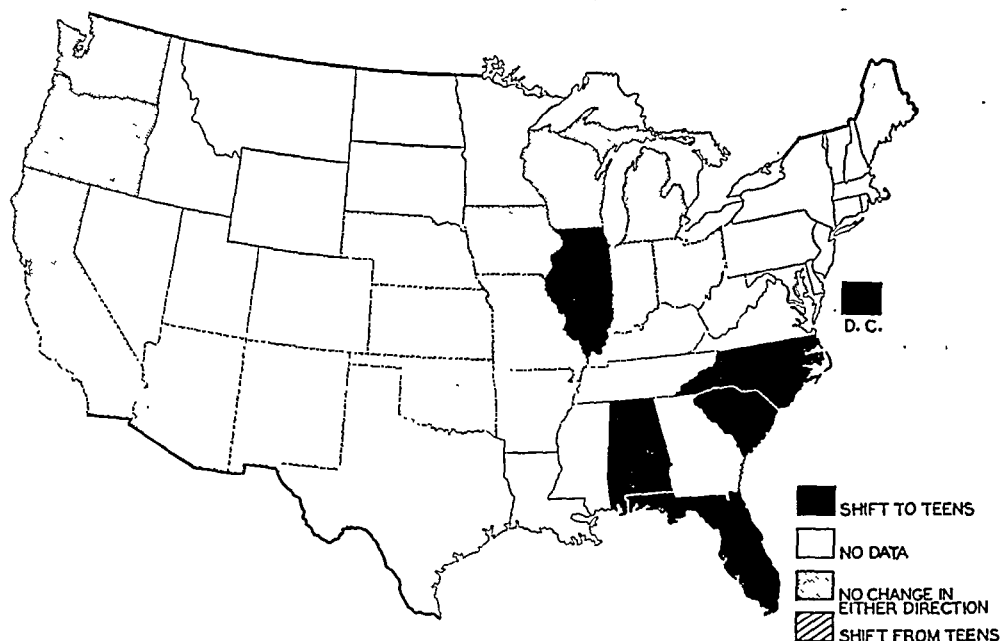

CHART 4—Changes in Age Distribution of Negro Females Infected with Syphilis Admitted to Public Clinics, 1941–1942

it was found that the changes taking place varied widely from one place to another, a search was made for factors which might be possible causes of this disparity.

The two most obvious factors operating to change the populations of vari-

ous areas of the country during the period under consideration were: (1) the induction of large numbers of young men into the armed forces and their mobilization at various places for training and embarkation, and (2) the concurrent concentration of civilian

CHART 5—Changes in Age Distribution of Negro Females Infected with Syphilis Admitted to Public Clinics, 1942–1943

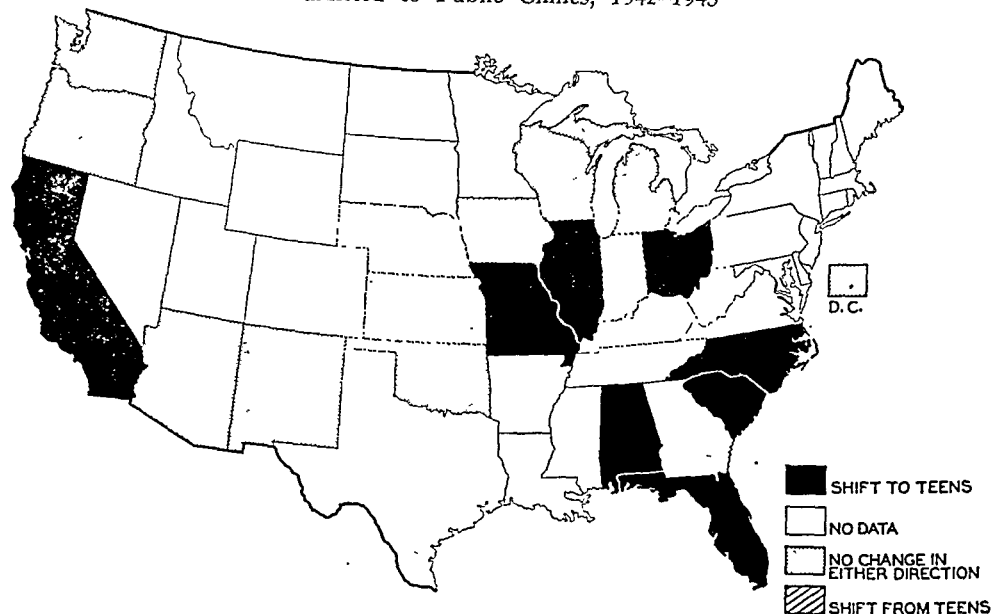

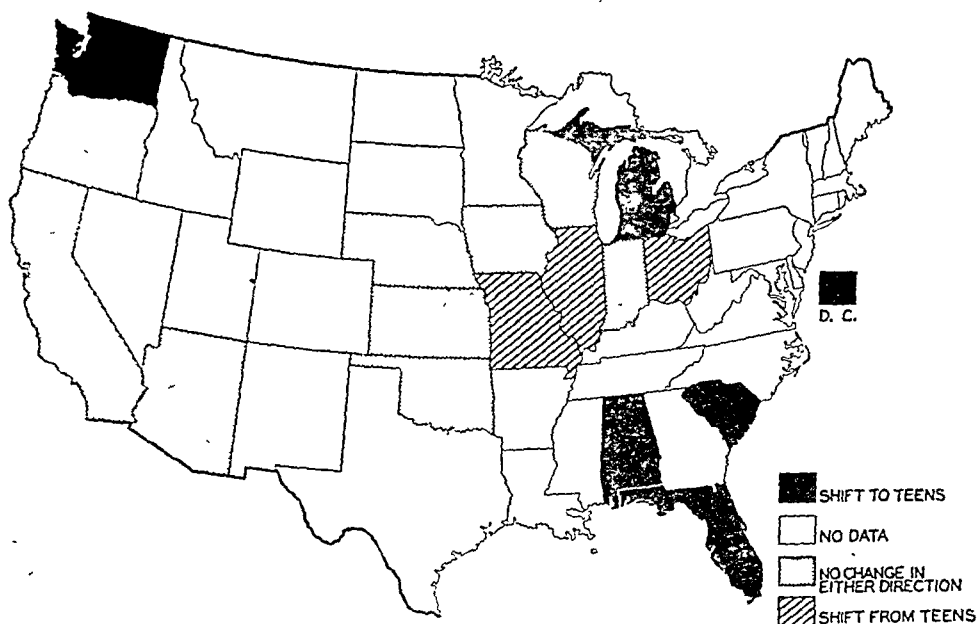

CHART 6—Changes in Age Distribution of Negro Females Infected with Syphilis Admitted to Public Clinics, 1943–1944

population where war industries were being developed. Both of these changes, of course, led to a corresponding decrease in population in non-strategic areas.

Military movements did not change the populations of individual states to any appreciable degree until the period 1942–1943.^{7, 8} By 1943, the peak year of concentration in the United States, military personnel comprised over 5 per cent of the population in 12 of the 20 states included in this study. This minimum proportion takes on added significance when it is considered that it included persons in high venereal disease incidence age groups living in an unstable social environment. After 1943, with the shipment of troops abroad, the military population declined. By 1944, military population constituted 4.5 per cent of the whole population as compared to the 5.2 per cent in 1943.

Since 1940 there has been a movement of civilians toward centers of industry.^{7, 8} Estimated civilian population figures as of November, 1943, showed that 82 of the 137 metropolitan

districts of the United States increased by 10.4 per cent while the remaining 55 decreased by 5.6 per cent.⁸ Due to the fact that many men had been removed from civilian life, a great proportion of this increasing concentration at war industry points was made up of women. There was an 11 per cent increase in female population in urban areas from April, 1940, to July, 1944.⁸ The number of women employed in the United States rose from approximately 12 million in December, 1941, to 16½ million in March, 1944.⁹ Furthermore, 29 per cent of women employed since December, 1941, have been under 20 years of age as compared with 3 per cent of those who were employed in March, 1941, and December, 1941.⁹ Therefore, since women have played an increasingly important rôle in industry during the four years under consideration, and have been employed at an earlier age than formerly, it is reasonable to believe that a large number of teen age girls were included in the labor movements.

Charts 7 and 8 show the above changes in civilian and military population graphically, in association with

the changes in age distribution of female infections with syphilis. The patterns for the two races turned out to be entirely different. Chart 7 presents the situation among white females and Chart 8 that among Negro females.

A tendency toward an earlier age of infection among white females seems to be definitely associated with an increasing civilian population. Part of this, of course, may be due to the uncovering of a greater proportion of existing teen age infections by preemployment and other industrial blood testing programs. When the years 1941 and 1942 are compared, every area in which there was a teen age shift showed an appreciable increase in population. It is true that the District of Columbia, with a great civilian increase in population, showed a shift away from the teen ages; this, however, is actually not a contradiction but rather can be considered as confirmatory evidence, since practically all the population increase in the District of Columbia consisted of older individuals. There is little or no industry in Washington, and the lower age limit for government workers is 18.

When 1942 and 1943 are compared, the association is not so clear as in the previous year, but is still noticeable. And, in 1943 and 1944 the relation between the increase in industrial population and early infection with venereal disease becomes much more apparent. In the two areas in which there were significant shifts toward the teen ages, the civilian population increased more than any other area. And the area that showed a significant shift away from the teens experienced a slight decrease in civilian population.

Increasing military populations seem to have little or no tendency to be associated with an increased proportion of teen age infections among white females. There is no doubt that this is in large measure due to the effective

venereal disease control measures carried out by the military authorities in coöperation with civilian agencies. From 1941 to 1942 the teen age shift among whites did occur in those states showing the greatest increase in military population, but these were the states that also showed increased civilian populations.

Furthermore, in 1942 and 1943, no association was found between teen age infections and increasing military population, and in 1943 and 1944, it becomes clearly apparent that the shift is much more closely associated with civilian population increases. In the two areas in which there were significant shifts to the teen ages, the military population decreased, and appreciable increase in military population took place in the one area which showed a significant shift from the teens. These observations become even more significant in the light of the fact that at the end of 1942 the draft was extended to include boys 18 and 19 years of age.

The pattern for the Negroes was not so consistent as that for the whites. In 1941 and 1942 there was a clear association between an increasing military population and teen age shifts, but none between civilian increases in population and such shifts. In 1942 and 1943 there is still an apparent tendency for an earlier age of infection in areas with increasing military population, and still no association with civilian increases. However, in 1943 and 1944, the pattern resembles that of the whites, with increasing civilian population rather than increasing military population being the most noticeable influencing factor.

Actually of course, it is probably true that the Negro pattern is not so very different from that of the white, since most of their industrial movements did not take place until more recent years when the labor shortage became very acute. Most of the Negro industrial population movements did not take

place until 1943, and it is in the comparison of 1943 and 1944 that we find the greatest changes in the age at which syphilis is acquired.

In California for 1942 and 1943, and in Alabama for 1943 and 1944, the age pattern differed from the other areas. They have both been shown on the charts as a shift toward the teens. However, what actually occurred was that there was a shift both toward the teens and toward the older years away from the twenties. In both of these states the explanation might very well be that there are two types of shifting labor, industrial and agricultural.

The public health significance of these data is readily apparent. Throughout the war period it has been more or less accepted as a fact that concentration of military forces in an area constituted the chief venereal disease control problem to be met. The data which have just been presented, however, do not warrant any such assumption. Rather it is the occurrence of unusual industrial activity which represents the graver epidemiologic venereal disease problem. This is understandable when we think of the growing proportion of young immature girls being employed in industry and the almost necessarily transient nature of the present-day industrial portion of our population. Sir William Beveridge has listed as one of the three necessary¹⁰ conditions of full employment the "organized mobility of labour," and the present Congress is considering measures to insure full employment in this country.

It seems indicated that more intelligent program planning is possible from study of the population groups encountered or expected in an area of health jurisdiction. For instance, venereal disease activities should be strengthened wherever an appreciable expansion in industry is anticipated. Furthermore, it might be well for health officers to study the general public

health problems inherent in a transient population which follows changing employment opportunities from one section of the country to another. The removal of the individual from the usual restraining influences of a familiar environment introduces other health hazards in addition to the venereal disease, for example tuberculosis and the nutritional diseases.

The implementation of a complete program which will control these ills depends, of course, on many agencies other than the health departments. Their prevention will lie in good part with welfare and social agencies within the community. The exposure rate rises with the removal of young girls from their homes and from school to overcrowded areas without adequate housing, recreation, and other normal living conditions. The provision of healthful places to live, normal places to play, and opportunities for further education depends on the activities of agencies concerned with the social welfare. To this the health departments must add good epidemiology and treatment of all disease. A well rounded and thoroughly adequate program depends upon the close integration of all these factors.

The Use of $2 \times n$ Chi Square in the Analysis of Change in Age Distributions

PAUL T. BRUYERE, M.D., M.P.H., MARTHA C. BRUYERE,
AND GERALDINE A. GLEESON

Division of Venereal Diseases, U. S. Public Health Service, Bethesda, Md.

RECENTLY the statistical section of the Venereal Disease Division, U.S.P.H.S., was confronted with the problem of determining whether persons under 20 were becoming infected with syphilis more frequently during the war period. There was available a large body of data consisting of tabulations for the years 1941-1944 showing the number of patients with early syphilis admitted to public clinics by age, race, and sex.

Various methods of analyzing the data were considered. Averages, such as the mean, median, or mode, together with their appropriate standard errors, are the statistics most frequently employed for determining changes in frequency distributions and measuring their extent and significance. All of these measures were discarded as unsuitable for the purpose at hand. The mean was not used because (1) it is unduly affected by cases occurring at extremely low and high age levels, (2) it is possible for changes in one part of the distribution to be balanced by changes in another part and thus not be reflected by any change in the mean. The median age, the point above and below which an equal number of cases fall, is the most commonly used average in analyzing data of this kind, because its insensitivity to extreme items makes it preferable to the mean. However, it

and the mode, which is the point at which the frequency is greatest, are basically merely division points in the distribution and do not depend on the values of the individual items. Therefore they quite often do not reflect changes which may be of considerable importance. Furthermore the standard errors associated with them are relatively large and are subject to certain theoretical restrictions which make them of doubtful value for the present purpose. Therefore, the mean, median, and mode were all considered to be inadequate for the statistical analysis of shifts in the age distribution of syphilis.

Instead of using averages, then, it was decided to consider the data as a whole by directly comparing the age distributions from one year to the next. To test significance of changes in these distributions, Chi square tests were set up for each pair of adjacent years. Where small numbers of cases were reported, age-years were combined in order to obtain a frequency of at least 5 in each cell; and in a few instances, it was also necessary to combine states for the same purpose.

The following formula for Chi square in a $2 \times n$ contingency table was developed in a form which gives the contribution of each pair of frequencies to the total Chi square and which is convenient for machine computation.

Total	3,316	100.0	3,211	100.0		65.51

$$p = .508044$$

$$q = .491956$$

$$\frac{1}{pq} = \frac{1}{.249935} = 4.001040$$

$$\frac{p}{q} = 1.632702$$

$$\frac{p}{q} + 2 = 3.032702$$

$$\chi^2 = \sum_j \left[\frac{f_j^2}{f_j + f'_j} \cdot \frac{1}{pq} + f'_j \frac{p}{q} - f_j \left(\frac{p}{q} + 2 \right) \right] \quad (a)$$

$$= \frac{\sum_j \left(\frac{f_j^2}{f_j + f'_j} \right) - \frac{F^2}{F + F'}}{pq} \quad \dots (b)$$

f_j = cases j years of age reported during the succeeding year.

$$F = \sum_j f_j$$

$$F' = \sum_j f'_j$$

$$p = \frac{F}{F + F'}$$

$$q = \frac{F'}{F + F'} \text{ or } 1 - p$$

Where f_j = cases j years of age reported during one year.

Formula (a) was used to obtain the

contribution of each item to the total Chi square. Formula (b) is equivalent to the familiar one developed by Brandt and Snedecor.¹ It was used to compute the total Chi square directly, the summation of the individual results obtained by the use of formula (a) serving as a check on the total Chi square from formula (b). The computations involve little more labor than is required for the means and standard deviations, since the individual contributions generally need be determined only when the total Chi square is found to be significant. If only the total is desired, the

$$\frac{f_j^2}{f_j + f'_j}$$

can be cumulated in the machine, and a convenient check can be obtained by repeating the operation with f_j and f'_j interchanged. The entire calculation is self-checking if the individual contributions to the total Chi square are determined.

Application of these formulae set up for the Negro females, 1941-1942, in the State of Alabama gave the results shown in Table 1. In analyzing the result of the procedure in this instance, it was determined by entering in the table of χ^2 with (n-1) degrees of freedom that the probability of occurrence of a Chi square as large as that found for the total distribution (65.51) was far less than .01, indicating that the age distribution of syphilis incidence in Alabama in 1942 was significantly different from the distribution in 1941. Furthermore, from the contributions of individual years of age to the total Chi square, it was readily seen that there had been significant increases in cases of early syphilis in the ages 14-19 years, with compensating decreases in the remaining age-years. For the same data, both the mean and median ages were lower in 1942 than in 1941, the median dropping from 21.4 to 20.7, and the mean from 23.0 to 22.2. Both of

$$p = .451724$$

$$q = .548276$$

$$\frac{1}{pq} = \frac{1}{.247669} = 4.037647$$

$$\frac{p}{q} = .823899$$

$$\frac{p}{q} + 2 = 2.823899$$

these differences are significant, being in each case greater than 2.575 times the standard error. These statistics, however, give no indication of the specific age-years undergoing changes in incidence.

In other instances the mean and median not only failed to give a complete picture of the situation but yielded results which were actually misleading. For example, among white females in the State of Michigan (Table 2) the median age fell from 25.2 in 1942 to 22.9 in 1943, and the mean age from 27.4 to 25.3. When tested for significance, the probabilities of each of these differences fell between the .01 and .02

limits in a table of relative deviates. However, Chi square tests on the same data proved that no specific teen-age year underwent a significant change, nor did the total Chi square indicate a significant difference between the 2 years.

On the other hand, in some instances, the Chi square test showed that a significant shift to the teens from older age-years had taken place, when both the mean and median failed to show any significant change. An analysis of the data for Negro females in New York City, 1942-1943 given in Table 3 illustrates such a case. While no individual age among the earlier age-years showed a highly significant change, the prob-

* Less than .005

ability of occurrence of so large a total Chi square fell between .01 and .02, indicating that a significant change had taken place in the entire distribution. The mean age in this group was 22.7 in 1942 and 22.4 in 1943; the median age was 21.5 in 1942 and 21.2 in 1943. These differences were not significant, the probability of the occurrence of each being well above .10.

These few examples serve to illustrate some of the advantages of the $2 \times n$ Chi square in the analysis of changes in frequency distribution.* As far as we have been able to determine, it has

not been extensively used for this purpose. It is, however, an excellent tool for such analyses, since it is sensitive to changes at any point in the distribution and is capable of indicating the points showing the greatest changes. For this reason it is more flexible and more productive of information than the mean or the median.

Report of the Chairman of the Executive Board of the American Public Health Association to the Governing Council—1945

ONE may draw some significant conclusions from a review of Association affairs covering the fifteen months that have elapsed since the Second War-time Conference in New York City in October, 1944, to the end of 1945. An atmosphere has been created in this 74 year old professional society which attracts new projects eminently suitable for development under its sponsorship. It is an atmosphere, further, which attracts the professionally competent, so that any project is assured of advancement under favorable auspices. It is an atmosphere which not only attracts but which holds both projects and persons until the job is done. The qualities of courage and farsightedness displayed by the Association have created the magnetism which brings into our sphere of influence the dynamic issues with which we have been dealing in 1945.

During this momentous period the world passed from deep preoccupation with war to deep preoccupation with peace. To no group of persons anywhere could the coming of peace mean more professionally and personally than to the world-wide fraternity of public health workers. To this Association it brought challenges at very practical levels, some of which I shall review in this report. Even though the manifold activities of the Association preclude a systematic account of all that has fallen within the purview of the Executive Board, I shall offer no apology for choosing certain matters for special

emphasis on which the Governing Council should be specially informed.

ACCREDITATION OF SCHOOLS OF PUBLIC HEALTH

The need for the raising of an authoritative voice with regard to facilities for educating and training for the public health professions has long been manifest, but it was never so urgent as in the spring of 1945 when the European war had ended and the war in the Pacific was coming to its conclusion. Greatly increased demands for public health training were foreseen through the removal of financial barriers in the United States by the G. I. Bill of Rights. There was also a proper concern on the part of the federal government to assure to veterans an adequate return on scholarship funds. The Committee on Postwar Training and Recruitment of the U. S. Public Health Service and the Association of Schools of Public Health turned to the Association and invited it to undertake a program of accreditation of institutions considered competent to offer courses for postgraduate training in public health. The Committee on Professional Education, under the Chairmanship of Dr. William P. Shepard, has had this subject under consideration since 1942 and, with the approval of the Executive Board, it accepted the task.

An editorial in the September issue of the *American Journal of Public Health* described the situation which has ex-

isted in North America, outlined the proposal to the committee and the plan of procedure adopted. The Commonwealth Fund has generously assured the financing for three years. With Professor C.-E. A. Winslow as Consultant on Criteria and Assistant Consultants especially engaged for the visit to each institution, this project advanced during the year to a point where institutions accredited by the Association to give the Master of Public Health degree (Diploma in Public Health in Canada) could be announced early in 1946, in our official *Journal* and elsewhere, together with the criteria governing accreditation. The next move is in the direction of accrediting institutions to give the Doctor of Public Health degree and thereafter to extend the program to consideration of other graduate training and perhaps to field training centers. If there be any fear that the attainment of these objectives will result in a pattern of conformity which will leave no room for experimentation and imagination in our schools of public health, it may be dispelled by the philosophy of the Committee on Professional Education so well expressed by its Chairman: "Just as the committee recognizes that requirements for professional qualifications of public health workers must be fluid, so it recognizes that teaching in schools of public health must remain dynamic and free from the confining influences of rigidly prescribed curricula or standards. Hence the committee is resolved that its accreditation shall be an incentive to experimentation and diversity rather than an influence for forcing education for the public health professions into a uniform mold. It will suggest only very broad principles both of organization and of curriculum, but will insist on a set of minimum criteria representing the best consensus of opinion of both teachers and practitioners."

The accreditation program is an ex-

ample of the kind of responsibility which is entrusted to the Association and which it is equipped to assume and discharge with distinction.

VOCATIONAL COUNSELING AND GUIDANCE PROGRAM

When the war ended, more than 1,000 members of the Association were in one or another of the military services. With many the future was as secure as futures can be in this uncertain world. They would return to the positions they had held previously in public health. With others too young perhaps to be established before they put on the uniform, or with inclinations altered as a result of new influences, there appeared to be opportunity for expanded usefulness through the Association's Employment Service if it could be strengthened by full-time trained personnel in the Central Office. While the Executive Board and the Committee on Professional Education were considering how this could be done, the U. S. Public Health Service, faced with hundreds of inquiries from returning veterans regarding post-war opportunities in public health, saw the advantages of single agency handling of such matters, and was receptive to a coöperative arrangement with the Association to make it possible. As a result, a Vocational Counseling and Guidance Service has been established in the Association for public health workers and employers. With federal funds well trained consultants have been attached to the Central Office staff to supply information and advice. The staff supplies not merely information as to existing jobs, but as to qualifications and training opportunities for the various public health specialties. The Executive Secretary continues, as formerly, to give personal attention to employment and counseling service. In this undertaking there is continuous and close coöperation with the Public Health Service

through the Surgeon General's Committee on Postwar Training and Recruitment. While the first emphasis was upon the veteran, it was soon apparent that the large number of vacancies could not be filled with qualified personnel from this category alone, and the base of operation widened spontaneously to include non-veterans as well.

On December 31, 1945, the Employment Register listed 150 openings offered by 75 employers and 105 trained candidates for positions. Intensive efforts are being carried forward to make known the availability of the service and to stimulate state and city health departments to make full use of it in building up depleted staffs.

An activity related to the Counseling Service is the brochure, *Employment Opportunities in Public Health*, published by the Committee on Professional Education at the request of the War Manpower Commission. Of the 15,000 copies printed, 13,000 were made available to the U. S. Public Health Service and to the War Manpower Commission for use in Separation Centers. Another pamphlet, *Careers in Public Health*, is in preparation, also under the supervision of Dr. Shepard's committee, designed for the use of vocational counsellors in high schools and colleges. It will be published and distributed before the end of the present academic year.

NEW ACTIVITIES OF THE SUBCOMMITTEE ON MEDICAL CARE

When the Governing Council last met, on October 2 and 4, 1944, the most important item on the agenda was a Report on Medical Care from the Committee on Administrative Practice. The report was approved by a large majority and has since been widely distributed as an official declaration of the Association, affirming the Association's belief that a program of medical care designed

to reach all the people is essential and its conviction that an overall program can be realized within ten years. The declaration proposed a simultaneous attack on five fronts—(1) development of administrative organization to provide services; (2) facilities for distribution of costs; (3) advancing the training of personnel; (4) promoting construction of facilities; and (5) the improvement of knowledge. From this action of the Governing Council have stemmed two important developments just now arrived at a stage where they can be announced, after months of preliminary negotiation and planning.

The first will implement the work of the Subcommittee on Medical Care directly. The subcommittee, through the generosity of the Rockefeller Foundation, becomes the recipient of a financial grant to establish an office with full-time technical staff, and it will turn its attention immediately to a review of proposed federal and state health legislation, recommending to the Association the stand it should take with regard to such legislation in the light of its declared principles. The subcommittee will provide information on medical care problems to the public health professions, and will attempt to stimulate leadership in the formulation and administration of medical care programs. Later on, the subcommittee hopes to formulate in detail the specifications at the technical level of good medical care programs and to describe the steps by which such programs can be established, including organization, financing, and administration. The subcommittee's initial tasks are basic to a complete understanding of the problem and to its ultimate solution.

The second development will aid in the achievement of the objectives of the Association's declaration through focus on one of them—that of the extension of knowledge. The Executive Board has approved a plan whereby the

Albert B. and Mary Lasker Foundation will annually provide a number of awards, to be given by the Association, designed to shorten the time between a scientific discovery in the field of medicine or public health and its general use in practice, particularly in a preventive way. Dr. George Baehr has accepted the chairmanship of a committee now in process of formation to chart the activities, within the interests of the Association, which these awards are planned to stimulate. First priority will be given to research with relation to the diseases which are the leading causes of death. There is also opportunity to recognize administrative achievement in the prevention and treatment of these diseases. The need for increased information among the public health professions about the causes, treatment, effective care, and prevention of these most serious diseases is obvious. The Board believes that the awards will be of value in stimulating professional effort in all these areas and in contributing to public knowledge concerning them. The contributions of health agencies or of individuals are of equal importance in the aim of the Lasker Awards. It is hoped that one or more of these awards may be conferred for the first time at the 1946 Annual Meeting.

CONDUCT OF ASSOCIATION BUSINESS IN THE ABSENCE OF AN ANNUAL MEETING

The year 1945 was the first in the Association's history when no Annual Meeting was held. The end of the war did not clear hotel and transportation facilities for convention travel even when Office of Defense Transportation regulations were removed and the Executive Board reluctantly assumed the responsibility of breaking the long tradition. Accepting the fact that an Annual Meeting in 1945 was an impossibility, the Executive Board set up

a procedure for conducting necessary Association business with the Governing Council by mail. With regard to the terms of officers and committee members, it invoked Article IV of the Constitution which provides that "all officers shall serve until their successors are elected and qualified." This has had the effect of holding in office for another year all elected and appointed persons whose terms would otherwise have expired in 1945.

PARTICIPATION IN STATE AND REGIONAL MEETINGS

In partial substitution for an Annual Meeting, the Association coöperated in ten state and regional meetings. The successful tour of Western state public health association meetings with a team of speakers organized by the Executive Secretary was repeated for the third wartime spring, and in December a Victory Meeting was held in collaboration with the Public Health Association of New York City. The total attendance at these ten meetings exceeded the attendance at any of our Annual Meetings in the past. Begun as a wartime measure, there are elements of special stimulation and encouragement, particularly to the younger workers who do not have the opportunity to attend a national meeting, that point to the continuation of the traveling team of speakers in the future.

THE AMERICAN JOURNAL OF PUBLIC HEALTH

A year without the more than 200 papers and reports supplied by an Annual Meeting has had no effect upon the *Journal*, contrary to expectations. Under the able leadership of the Editor, Professor C.-E. A. Winslow, a series of especially invited historical reviews was initiated. Two have already appeared—"Evaluation of Methods to Control Air-borne Infections," by Dr. James E. Perkins, in September, "Tsutsugamushi

Disease in New Guinea," by Dr. Kenneth F. Maxcy and others in November. "Blood and Blood Derivatives," by Dr. Charles A. Janeway, is scheduled for January, 1946. Others in hand concern the Rh factor, The Public Health Aspects of Birth Control, and Insecticides, respectively. The Sections have stimulated many contributions, and these and the excellent unsolicited manuscripts reaching the Editorial Board because of the *Journal's* reputation as the most authoritative and influential magazine in its field have provided all the material necessary for the 1945 volume.

The *Journal* quietly celebrated its 35th birthday this year with a historical article in the December issue entitled "The Journal Is 35 Years Old." The average circulation of the *Journal* in 1945 was 13,300, exceeding by 811 its best previous record which was made in 1944.

SECTION ACTIVITIES

A meeting of Section Secretaries was financed by the Association early in the year to consider how the energies of Section Committees and members might be directed in a year lacking the stimulation of an Annual Meeting. In addition, four of the Section Councils—Engineering, Food and Nutrition, Health Education, and School Health have met for the same purpose. The results have been noteworthy. Section work has gone forward unabated; the deadline, which it was believed the Annual Meeting represented, apparently being only incidental.

The newest Section, that on Dental Health, has undertaken a source book on Public Health Dentistry now being written by a group of some 18 editors, chiefly dentists, but including also experts in health education, medical economics, and public health administration. A contract has already been signed with a commercial publisher for

publication, with arrangement for royalties to the Association.

The Vital Statistics Section has published a directory of vital statisticians including about 900 names, a by-product of which was to bring 50 new members into the Association. It is also sharing with the Epidemiology Section membership on a Subcommittee on Morbidity Registration and Statistics of the Committee on Research and Standards. The lack of widespread morbidity reporting has long made it impossible to evaluate completely the effects of public health service, or indeed to chart accurately the needs. Particularly is this true with the present increasing importance of chronic and deteriorative diseases of an aging population.

From the Laboratory Section has come a second edition of *Diagnostic Procedures and Reagents* and a condensed Spanish edition of the eighth edition of *Standard Methods for the Examination of Dairy Products*. The ninth edition of the latter is in preparation, as is the ninth edition of *Standard Methods for the Examination of Water and Sewage*. Each is scheduled for publication before the next Annual Meeting.

The School Health Section has had an active year. It has served as one of the fourteen agencies coöperating in the publication of *School Health Policies*, a restatement and bringing up to date of current thinking with respect to health service in schools. It has organized a Rural School Health Committee, and committees to study school health legislation and preservice and in-service training of school health personnel.

The Public Health Education Section has developed a wholly new technique of committee work. In an experiment designed to increase member participation in Association and Section activities, and at the same time to

develop "grass roots" interest, its Section work has been carried on through six regional committees, each studying the resources and problems of the area in which the members live. The committees are composed of all the members of the Section in a given area. It is planned that at the Annual Meeting of the Association in 1946, the Section program will be based on this regional organization, which will give an opportunity to exchange diverse experiences and weld them into common objectives, though variously manifested.

THE STANDING COMMITTEES

Committee on Professional Education

We have discussed the Accreditation project and indicated that it resides in the Committee on Professional Education. This alone would be sufficient to engage fully the voluntary efforts of the Chairman and his colleagues, but it is only part of the story. The Merit System Unit, conducted also under the Committee on Professional Education and operating from the Central Office, has made marked progress in 1945. The Unit with the coöperation of the U. S. Public Health Service and the Children's Bureau is now ending the fifth year of its work. During that time it has sold or released a total of 163 examinations for 22 state and 2 city health departments, 54 since April, 1945. There are orders on hand at the moment for another 15 examinations. The Unit now has a stock pile of examination items in eight fields of public health—public health administration, environmental sanitation, public health nursing, public health laboratory service, vital statistics, medical social work, and beginnings have been made in health education and nutrition. This year approximately 22 per cent of the Unit's operating costs were recovered in examination fees, a proportion that will increase in future years because of the constantly accumulating file of items.

Public health nursing examinations have been provided most numerous, the figures being 91 examinations in 21 states. The laboratory field is next with 50 examinations provided for 8 states and one city. Environmental sanitation is third with 30 examinations provided for 7 states and 1 city.

Recent activity of the Merit System has not, however, been limited to meeting the increased demands for examinations. During the past year the program has been expanded to include three new major subject matter areas, namely, medical social work, vital statistics, and health education. At the same time specialized material has been prepared in a number of smaller areas, as, for example, clinical pathology, entomology, physiotherapy, food and drug chemistry, and x-ray technique. The development of these new fields brings to a total of 332 the number of public health persons who have participated in the project either as constructors or reviewers.

One of the most important developments during 1945 has been the statistical evaluation of the examination material. Ten of the 22 states using Merit System Unit examinations have returned data to the Central Office and, with the addition to the staff of a statistician on a half-time basis, maximum use of this information has been made.

The Committee on Professional Education from 1937 to date has prepared reports on educational qualifications for 15 professional categories in public health which the Governing Council has approved. The latest reports—Educational Qualifications of Public Health Dentists and Educational Qualifications of Executives of Voluntary Health Associations were adopted as proposed reports by the committee in October, 1944, were published in the *Journals* of January and May, 1945, respectively, and at the end of the year, through a mail poll, in the absence of the Annual

Meeting, were approved by the Governing Council as recommendations of the Association. Nearly all are currently under revision in conformity with the well established policy of the committee. A report on Nutritionists in Health Agencies, originally adopted in 1941, will soon be before the membership for comment in revised and extended form. It is being published in the January, 1946, *Journal* as a Proposed Report and at the same time in the official Journals of its co-sponsoring agencies, the American Dietetic Association and the American Home Economics Association.

Permission has been granted for translation into Chinese of the reports on Qualifications of Public Health Laboratory Workers and Health Educators, and to the Coordinator of Inter-American Affairs for translation into both Spanish and Portuguese of the report on Health Educators. The circulation of all reports of the Committee on Professional Education, including their publication in the *Journal*, approximates the 200,000 mark. The concerns of the Committee on Professional Education for 1945, therefore, have involved professional qualifications of public health personnel, the promotion, extension, and interpretation of merit system methods for all such personnel, recognition of acceptable training institutions, and recruitment policies that will result in an increasing body of trained and equipped personnel for public health leadership today and tomorrow. The Chairman and the committee are aware that this quartet of activities needs to be supplemented by a fifth, namely a knowledge of and concern for the salary standards current in public health. The committee is committed to a salary study and is planning for it in the coming year.

Committee on Administrative Practice

The Subcommittees of the Commit-

tee on Administrative Practice, Wilton L. Halverson, M.D., Chairman, in addition to that on Medical Care mentioned earlier, include Local Health Units, Evaluation of Administrative Practices, Accident Prevention, and State and Local Health Administration. Under the supervision of the last named, the field work has gone on without interruption, even with an interval of several months between the resignation in July of Dr. George T. Palmer, Associate Field Director, and the recent appointment of his successor, Roscoe P. Kandle, M.D., M.P.H. From October, 1944, to December, 1945, public health studies have been made in Madison County, Illinois, in San Francisco, in Sacramento, and state studies in Utah, Idaho, and Colorado. This subcommittee also is responsible for enlarging the Reporting Area through the use of the *Evaluation Schedule*, and the results of its work are most encouraging. Of 145 schedules submitted from 18 states in 1945, 47 were from communities participating for the first time. The expansion of *Health Practice Indices*, which shows the range of accomplishments in various fields of community health service, also indicates the spread of the Reporting Area idea. The second edition, published in 1944, contained data concerning 178 communities; the third, published in the fall of 1945, charts the accomplishments of 243.

Under the auspices of the Subcommittee on Local Health Units, Haven Emerson, M.D., Chairman, and published for the Association by the Commonwealth Fund, *Local Health Units for the Nation* appeared in August, and within a month was in its second printing. This is the result of a two year study financed by the Fund. Its recommendations would create 1,197 local health units providing minimum essential health services to all the people at a cost of \$1.00 per capita,

replacing 18,000 local administrative units now in operation and under which 40,000,000 persons are still without basic health protection. There appears to be a real demand for further exploration and promotion of the principles suggested by the subcommittee. Not only have varied national magazines such as the *American Journal of Public Health*, *The American City*, *State Government*, and the *Public Administration Review* solicited articles, but the report has also been reviewed in such journals as that of the American Medical Association, the *Public Policy Digest* of the National Planning Association, *Public Health Reports*, and *New York Medicine*. A number of the state health departments, notably California and Colorado, have prepared and published full digests of the report, both as to its general principles and their application to the respective state situations.

A follow-up institute of state health officers and directors of local health administration is planned during the coming year to exchange information, develop activity, and influence professional and public opinion in favor of early completion of the total coverage of the nation with full-time local health units.

The work of the Subcommittee on Evaluation of Administrative Practices has been confined this year to the Study Committee on Whooping Cough, under which extensive studies of antigen have been conducted by Dr. Pearl Kendrick, and to the reorganization of the Study Committee on Goitre. The death of the Secretary of the latter, Dr. Fred B. Miner, is recorded with regret. His successor is Dr. O. P. Kimball. Reports from both Study Committees are looked for in 1946.

The Subcommittee on Accident Prevention, Donald B. Armstrong, M.D., Chairman, has developed a plan for the integration of home safety activities in programs of state and local health de-

partments which was published in the *Journal* in March. In the same issue there was published an article under Dr. Armstrong's authorship entitled "Accident Prevention — An Essential Public Health Service."

The Committee on Administrative Practice is now 25 years old and its quarter-century anniversary was commemorated in the December *Journal* by the publication of a historical review of its accomplishments. The Executive Board salutes the committee, the many persons and agencies who made it possible, and the financial supporters without which nothing could have been done. During 1945, the Commonwealth Fund and the general Association budget have provided the sinews of war. Under a new plan which will go into effect in 1946, additional Association funds will be made available to the committee so that subcommittees in addition to that on State and Local Health Administration, whose activities will continue to be financed by the Commonwealth Fund, may have opportunity to meet and carry out ambitions it was not possible before to encourage. The American Drug Manufacturers Association has recently renewed the financing of the pertussis study through contributions from seven of its members.

Committee on Research and Standards

The Committee on Research and Standards, Kenneth F. Maxcy, M.D., Chairman, can point with pride to the activities of its subcommittees. Among these is the Subcommittee on Communicable Disease Control, of which Haven Emerson, M.D., is chairman, whose outstanding contribution has been the revision and extension of the report on the *Control of Communicable Diseases*, Sixth Edition. This was prepared in coöperation with representatives of the British Ministry of Health, and is official with the U. S. Public Health Service, U. S. Navy, has been approved

in principle by the Surgeon General of the Army and by the United Nations Relief and Rehabilitation Administration, and has been recommended for adoption as an official statement by the National Health Administration of China and by the Dominion Health Council of Canada. Seventeen state and local health departments have distributed it over their own imprints. Other state and territorial health departments, as well as South American countries, have made it official. About 100,000 copies have been printed in English. The Office of War Information has had it translated into Italian, French, and Thai, in a total of approximately 150,000 copies. The Pan American Sanitary Bureau has undertaken the translation into Spanish and Portuguese. A Chinese translation is also under way.

The work of the Subcommittee on Food Utensil Sanitation under the chairmanship of Walter D. Tiedeman has moved forward during the year because of the fortunate opportunity of developing relationships with the National Sanitation Foundation, which has agreed to support a new project, in cooperation with the subcommittee, for the evaluation of dishwashing devices, both in terms of physical aspects and chemical and bacteriological controls. It is appropriate that the coöperation of the National Sanitation Foundation in providing meetings of this group be properly acknowledged.

The Subcommittee on Morbidity Registration Statistics, Lowell J. Reed, Ph.D., Chairman, has advanced its purposes very rapidly through the meeting of an International Committee on Morbidity Registration, appointed by the United States Department of State, in fulfillment of a request made by the Mixed Commission in 1938. This committee has been meeting continuously over the past several weeks in Washington.

The Chairman of the new Subcommittee for the Evaluation of Methods to Control Air-borne Infections, James E. Perkins, M.D., approached his task by writing a review article for the *Journal* on the present situation. He has had two meetings of his subcommittee in 1945, with real progress reported.

The names of the members of this and other committees appointed since the April *Journal* went to press will be published early in 1946.

The Subcommittee on Hygiene of Housing, Professor C.-E. A. Winslow, Chairman, has rendered consultant service to the Memphis Health Department, the Philadelphia City Planning Commission, the St. Louis Health Department, and the Milwaukee Health Department. Part I of *An Appraisal Method for Measuring the Quality of Housing; A Yardstick for Health Officers, Housing Officials and Planners* was published in 1945 and has had gratifying acceptance. The National Association of Housing Officials has endorsed the method and is urging housing authorities to undertake surveys using its techniques. Parts II and III of the *Appraisal Method* are ready for the printer and will be published in 1946.

The Committee on Research and Standards has before it the reviewing responsibility, in advance of recommendation to the Governing Council, for promulgation as Association standards, of the Ninth Edition of *Standard Methods for the Examination of Water and Sewage*, and the Ninth Edition of *Standard Methods for the Examination of Dairy Products*.

Committee on Eligibility

The Committee on Eligibility has approved during the year over 1,000 applicants for membership, and at a meeting held in New York in October with representatives of all Sections of

the Association present it approved 121 applicants for Fellowship, 7 applicants for life membership, and the South Dakota Public Health Association as an affiliated society. The sudden death of the Chairman, Don W. Gudakunst, M.D., on January 20, 1946, is recorded with regret.

PUBLICATIONS

The Association has had a busy publication year. Books and reports have been mentioned in their proper places, but they are brought together here for the sake of the record.

An Appraisal Method for Measuring the Quality of Housing, Part I

Bibliography on Public Health and Allied Subjects (23rd edition)

Control of Communicable Diseases (6th edition)

Diagnostic Procedures and Reagents (2nd edition)

Employment Opportunities in Public Health Health Practice Indices (3rd edition)

Local Health Units for the Nation (Published by the Commonwealth Fund)

Spanish Summary of 8th Edition of Standard Methods for the Examination of Dairy Products

Vital Statistics Directory (3rd edition)

In the distribution of the Association's publications, as well as those of other agencies in the public health field, the Book Service continues to be a vital part of the Association. It has just completed one of the most active years in its 24 year history, having had a larger volume of business in terms both of number of books and reports distributed and in dollar volume. The 23rd edition of the *Bibliography on Public Health and Allied Subjects* (17,000 copies) has just been printed and is being distributed to members and subscribers. The demand for the 8th edition of both *Water Analysis and Milk Analysis* has been so great that war-time editions in paper covers were necessary pending the new editions expected off the press late in 1946. *Control of Communicable Diseases* and

Local Health Units for the Nation are among the best sellers month after month. But the Book Service also supplies members and others with free material, the *Bibliography* already mentioned, and reprints of *Journal* articles, especially the popular reports on professional qualifications of public health workers by the Committee on Professional Education.

MEMBERSHIP

It cannot be said too frequently that the strength of the Association lies in its membership and the voluntary service of its members to their professional society. Year after year we are able to report a new all-time membership record as qualified persons working in public health and in its related fields recognize what they can give to the Association and what the Association can give them. The membership at the end of 1945 exceeded that of any previous year by 353. On December 31, the total number of members was 9,408. Of these, 1,633 are Fellows. Included also are 26 Affiliated Societies, 36 Sustaining Members, of whom 5 were elected in 1945, and 16 Honorary Fellows. Sixty-nine applications for life membership are pending, and if these are favorably acted upon, the total number in this class will be 281. The membership figure of 9,408 includes also the 500 men and women in the military services whose dues were cancelled for the duration. It is gratifying to see how quickly these members reestablish their affiliation on a paying basis as soon as they are released from service.

FINANCES

The Association income for 1945 has been nearly \$225,000 and expenses have been approximately \$210,000. Income from membership has been the highest in the Association's history and this is also true of the *American Journal of*

Public Health and the sales of Association publications.

ACKNOWLEDGMENTS

The Executive Board takes this opportunity to acknowledge with great appreciation grants from donors, including the Commonwealth Fund, for appropriations to the State Studies and to the Subcommittee on Local Health Units of the Committee on Administrative Practice, and to the Accreditation Project conducted by the Committee on Professional Education; the Milbank Memorial Fund, the National Tuberculosis Association, and the Field Foundation for grants to the Committee on Hygiene of Housing; the Albert B. and Mary Lasker Foundation for a grant for awards to be given by the Association; and to the Rockefeller Foundation for a grant for the work of the Subcommittee on Medical Care. Acknowledgment to Sustaining Members for continued support to the entire Association program is gratefully made.

There is no activity of the Association which is not of the membership, by the membership, and for the membership, and this Report would be incomplete if it did not pay tribute to the hundreds of persons whose thought,

time, and hard work have contributed to the Association's progress this year. The Governing Council, the Executive Board, the Sections, the Standing and other Committees have had continuing responsibilities and therefore the widest opportunity to influence our policies and program. Many others have been called upon briefly for special service; still others, working alone and spontaneously, have done much to increase Association membership and otherwise extend the usefulness and prestige of the organization. The response from organized groups and individuals alike has been magnificent. This is the priceless ingredient of the atmosphere referred to at the beginning of this series of reflections. It can be depended upon as we face the known tasks of 1946 and those, now unforeseen, which will come our way.

Once more, as in years past, it is well to reiterate and to reemphasize that little or none of this record of activity and accomplishment would have been possible without the untiring, intelligent, and sympathetic administration and leadership by the Executive Secretary and his staff.

GOVERNOR DEWEY'S HEALTH MESSAGE

ON March 4, Governor Thomas E. Dewey delivered to the Legislature of New York State a special message formulating a new and comprehensive state health program. The recommendations of this message have now been enacted into law, and should mark a new milestone in the history of American public health. We congratulate Dr. E. S. Godfrey, State Commissioner of Health, and Chairman of the informal committee which developed this excellent and far-reaching program, and his associates in planning, particularly Mr. Homer Folks.

Perhaps the most immediately significant proposal of the Governor's message is a major increase of grants for the upbuilding of local health departments. As in other North Atlantic States, New York has for thirty years attempted to stimulate the establishment of full-time county health units—but with very limited success; at present, only 6 such units are in existence, out of a total of 57 upstate counties. No state grants have previously been offered to the larger municipalities. The bill calls for state-aid reimbursement for sums expended by county health departments up to 75 per cent of the first \$100,000 of the county budget and 50 per cent of expenditures above that figure. Furthermore, it provides for 50 per cent reimbursement for cities with a population of 50,000 or more. All in all, there is involved an appropriation of nearly three million dollars to New York City, nearly one million to other large cities of the state, and about a million and a half to the smaller communities. The inclusion of cities as recipients of state aid is an interesting new departure, which has perhaps special justification in the trend toward a flight of taxable capital from formal municipal limits to adjacent suburban areas.

In addition to these grants for public health services in general, Governor Dewey recommends new grants in a total of about six millions for "an all-out fight on tuberculosis with the objective of wiping out this dread disease in our state in twenty years or less." The state funds are to be used for an approximate 50 per cent aid in the care and treatment of tuberculosis, on a patient-day basis. As a condition of these grants, the "means test" as a condition for admission to approved tuberculosis hospitals would be entirely eliminated—"a tremendously

important psychological factor which will permit prompt hospitalization of patients, thus avoiding risk of infecting their families and others and also, by prompt treatment, saving countless lives."

A third extremely interesting proposal of the message is the establishment of an Interdepartmental Health Council to consist of the State Commissioners of Health, Social Welfare, Mental Hygiene, and Education and the chairman of the Health Preparedness Commission for joint planning in the areas of service where the jurisdictions of these officers may overlap. This is a timely recognition of the fact that public health, in its conventional sense, is not an isolated function but is intimately related at many points to more general problems of welfare and of education.

Passing over many minor and special phases of the proposed health program, there is one other provision which will be of special interest to our readers. This is a recommendation that the State Department of Health should establish a service for recruiting and training physicians and nurses for public health practice. Dr. Godfrey has already—with limited resources—pioneered along this line. An expansion of such training facilities would be of the greatest value, since the deliberations of our Committee on Professional Education have made it increasingly clear that the academic training provided in schools of public health should be supplemented by a definite period of supervised field training.¹

In 1914, with the reorganization of its State Health Department, under the guidance of Hermann M. Biggs, New York State gave inspiring leadership to other states. The carrying out of the program now proposed should again place the Empire State in the forefront of public health advance.

CASE FINDING IN THE CONTROL OF SYPHILIS

THE health officer who undertakes the control of syphilis discovers, very early, that he has but few tools with which to work and those of limited efficiency. Prophylaxis, case finding, treatment, and education are the only procedures theoretically available for his use.

Prophylaxis has had an excellent opportunity, in the Armed Forces, to prove its worth; its advocacy and use being tolerated because of the nature of the emergency. Under the most ideal conditions, however, it has had to be augmented by the repression of prostitution and other forms of sexual promiscuity, and by intensification of the civilian genitoinfectious-disease control program. There is reason to believe that the combination of procedures has very greatly retarded the spread of infection, but it has not kept the rates of infection from rising. In some theaters, as a matter of fact, they have been skyrocketing. It does not seem that there can be much hope for the control of syphilis by prophylaxis, in a disapproving and uncontrollable civilian population.

Case finding may be facilitated in several ways:

1. By public education to encourage suspicion of infection and prompt medical observation
2. By mass blood testing for case finding purposes
3. By routine blood testing and examination of all persons who come to medical attention, whether because of illness or for routine examination (as in pregnancy, for employments etc.)
4. By direct epidemiological case finding, starting with a known case

To be effective in preventing the *spread* of infection, case finding must find cases while they are still infectious; and it must tend to find them early so as to reduce the period during which infection may be spread; otherwise no substantial progress will be made in prevention.

By these criteria, case finding by public education is, potentially, the most effective procedure of them all. If every person who indulges in a questionable sexual relationship, and who shortly develops a genital lesion or a rash, would seek competent medical attention at once, innumerable infections would be brought under control. Although such a program for public and professional education should be pushed with vigor and intelligence, it cannot be anticipated that either the public response or medical diagnostic competence will shortly become adequate to the solution of the problem of syphilis control. This form of case finding will have to be augmented, for a long time to come, by other case finding procedures.

Mass blood testing is an expensive, a cumbersome and, to a considerable degree, a "shotgun" procedure. It is, in general, incapable of such regular and frequent repetition as to assure the detection of new infections as they occur and while they are still communicable. In areas where syphilis is extremely prevalent, such mass testing may be of value, as shown in a recent campaign of the Savannah-Chatham County, Georgia, Health Department.¹ Here, mass testing for both syphilis and tuberculosis was carried on simultaneously at a cost of about fifty cents for syphilis testing for each person examined and with 18 per cent of all persons tested positive.

Routine blood testing is a highly selective form of mass blood testing, and it has the same shortcomings as a case finding procedure in early syphilis. To the extent that it is used in the examination of sick persons, and is accompanied by competent physical examination and reliable history taking, it may lead somewhat more often to the detection of early infections.

Case finding by direct epidemiologic investigation is the most immediately effective and the most continuously applicable method for discovering infectious early syphilis. Given a patient with an open early lesion, it is among that patient's sexual contacts, within the limits of the duration of the infection and its incubation period, that other early infections are most likely to be found. For all practical purposes, syphilis is spread by a single form of contact, sexual intercourse. Unless the patient has been highly promiscuous, he (or she) should be able to recall most of those contacts over a considerable period of time. The search for contacts may, therefore, be carried on according to a definite pattern, along definite lines, with considerable potential hope for success.

It is true that there are many obstacles to this form of case finding. The patient often refuses to admit that he has been as promiscuous as he actually has been. The long incubation period of the disease permits the source of the infection to continue to operate, often for weeks, before a case comes to light and prompts search for the source and for all of the infections which have occurred in the meantime. (In this connection, the epidemiological follow-up of cases of gonorrhea may be of special value in leading more promptly to discovery of persons of promiscuous habits, likely to have, and to spread, both infections.) The variable length of the incubation period, combined with the promiscuity of the patient, makes it impossible, in many cases, to predetermine who, among all of the contacts, is the source; hence many persons must be identified, found, and examined, in the hope that the source will be among them. The trail is often

crossed by unrelated infections which lead away in new directions, but which must be followed through. Some of these are time-wasting cold trails of late, noncommunicable syphilis. The very promiscuity which spreads syphilis leads into the blind alleys of anonymity, and the more generally promiscuous the population involved, the greater the number of dead ends. (Case finding among the reported contacts of members of the Armed Forces was nowhere excitingly productive.)

In spite of its shortcomings, both experience and logic dictate the use of this procedure in the control of syphilis. Competent epidemiologists, working in communities with reasonably stable populations, and in which prostitution has been repressed, have enjoyed a very considerable success with this method. It will become constantly more effective as public and professional education improves, and more infections come to attention earlier to provide more starting points for direct case finding.

Treatment cannot contribute substantially to the control of the spread of syphilis unless case finding, by one method or another, has first produced *early* infections to treat. Once an infectious case is found, moreover, treatment must be adequate to the permanent control of communicability, or the end result of the case finding will be *nil*. Thus, case holding, to the point of permanent noninfectiousness, is an essential part of the process and cannot be neglected.

There is disturbing evidence that the rapid cure of early syphilis leaves the patient open to prompt reinfection; which is of relatively rare occurrence under the older, slower treatment schemes. Promiscuous persons may become repeated sources of new infections and pose new problems in case finding. In fact, if case finding is not speeded up beyond all previous performance, a cured patient may even be reinfected by the original source of his infection. This probability is so great in gonococcal infections that every attempt is now made to treat both the patient and his contacts on the same day! It seems clear that direct case finding must be promoted, expanded, and speeded up to the limit of its possibilities, or more ground may be lost than gained by the use of the more promptly and more completely effective therapies.

Important as it is to use these inefficient tools for the control of syphilis to the limit of their capacities for accomplishment, it remains a fact that no communicable disease has ever been controlled by case finding and case treating procedures alone. Unless a disease can be prevented from occurring at all there is little hope for its ultimate permanent control. The Scandinavian countries have now discovered that a population may be so disturbed during times of stress as to undo all that had been accomplished by case finding and treatment under more normal conditions. The rates of infection with syphilis have returned during the war in those countries to their 1920 levels.²

It is *not* the responsibility of the health officer, alone, to teach people how to behave or why they should so behave. The job must not be left entirely to the health department. Society knows very well that good sexual morality and sexual responsibility are essential to the preservation of the family and, therefore, of society itself. This would still be true even though syphilis and gonorrhea had never existed. It is to the interest of society to develop good sex character for its own sake. Sex character will never be built out of lectures on the dangers of infection with genitoinfectious disease, nor on the risks of becoming mothers out of wedlock, nor by the blackout of all discussion of sex. It will be built only out of a deep sense of sexual responsibility, such as that which finds its fullest

expression in the family. Sexual promiscuity is sexual irresponsibility. The place of the family as the indispensable unit of society cannot be secure so long as sexual irresponsibility is the order of the day.

MILTON JOSEPH ROSENAU

THE year which has just passed has been marked by heavy losses in the higher ranks of our leaders in the field of public health. Ravenel, Leathers—and now Rosenau are gone. Our sense of loss is mitigated only by pride in the fact that we have—in our professional field—the achievements of such outstandingly distinguished leaders to chronicle.

Milton J. Rosenau, President-Elect of our Association, was born in Philadelphia in 1869 and died at Chapel Hill at the age of 77, on April 9, last.

Dr. Rosenau took his medical degree at the University of Pennsylvania in 1889, and pursued his postgraduate studies in Berlin, Paris, and Vienna. His professional life was divided into three successive phases.

From 1890 to 1909, he served in the United States Public Health Service and for the last ten years of that time was Director of the Hygienic Laboratory. This Laboratory, which is now the National Institute of Health, owes its impetus and its high scientific standards largely to "M. J." The writer of this editorial happened to be a member of an advisory group under the Chairmanship of W. H. Welch, and heard Dr. Welch tell the then Secretary of the Treasury that there was no research institution in the world which was making a greater total contribution to medical knowledge than this United States Public Health Service Laboratory. Rosenau's own research on the standardization of tetanus and diphtheria antitoxin, on vaccine virus, his contributions to our knowledge of anaphylaxis, his studies on milk sanitation and milk pasteurization, and on the epidemiology of typhoid fever and acute respiratory infections was of a high order.

In 1909 Rosenau began the second major phase of his career as Professor of Preventive Medicine and Hygiene at Harvard where he continued to serve until 1935. Between 1913 and 1922, he, with W. T. Sedgwick and G. C. Whipple, directed the pioneer Harvard-Technology School for Health Officers; and between 1922 and 1935 he was Professor of Epidemiology in the Harvard School of Public Health. For seven years (1914-1921) he served also as Chief of the Division of Biologic Laboratories of the Massachusetts State Board of Health.

While in Washington Rosenau had published a book on *Disinfection and Disinfectants* (1901). At Harvard he made an important contribution in a work on *The Milk Question* (1912). A year later, in 1913, came his *magnum opus*, *Preventive Medicine and Hygiene*, which has remained not only the standard textbook in this field but one of the best examples of an ideal textbook in any area related to medicine. Its last (6th) edition was published in 1935. Dr. Rosenau received the Gold Medal of American Medicine for Service to humanity in 1912 to 1913, and the Sedgwick Memorial Medal of our Association in 1934.

Here was what seemed a full and successful life. Dr. Rosenau retired from

Harvard at the age of 66. He seemed broken in health and suffered from tragic bereavements. Then a miracle happened; and instead of resting on his laurels, he began a third wholly new phase of his career. He recovered his health and took the post of Professor of Epidemiology at the University of North Carolina. In the delightful environment of Chapel Hill he built up a new School of Public Health, now recognized as one of the accredited schools of our Association, and the pioneer institution of its kind in the Southeast. He was constructively active to the very end of his long life. Less than three months ago he went to Puerto Rico to represent the A.P.H.A. at the meeting of the Puerto Rico Public Health Association; and, even after his first heart attack in March, he took an active part in the Institute for Health Officers at Chapel Hill, jointly sponsored by the University and the A.P.H.A.

Dr. Rosenau's youthful vigor of spirit and his soundness of judgment will always live on with us who knew him as an inspiration. His erect, military carriage and his sardonic comments emitted with a piercing glance from heavy-lidded eyes might have been forbidding in another man—and indeed no one took liberties with M. J. But his winning smile prevented any sting; and he was the soul of kindness, always ready to go out of his way to help a pupil, a colleague, or a friend. Taking into account, not only his teaching for 35 years at two universities, but also his book on *Preventive Medicine and Hygiene* to which we all refer in time of need, it is probable that no single individual has ever taught so many public health workers so much as has M. J. Rosenau.

Fellowships in Health Education—1946

The U. S. Public Health Service has announced that fellowships for one year of graduate study in health education, leading to a master's degree in public health, are being offered to qualifying men and women by the U. S. Public Health Service through funds made available by the National Foundation for Infantile Paralysis.

Fellowships provide a year's study in public health education in an accredited school of public health, including an academic year of eight or nine months and three months of supervised field experience in community health education. A stipend of \$100 a month for the entire period of academic and field training, plus tuition and travel expenses for field experience, is provided. Travel to and from the university at the beginning and end of training is not included.

Fellowships are effective for the academic year starting in the fall of 1946. Those eligible to apply include men and women in sound health between the ages of 22 and 40 who are citizens of the United States and who meet the entrance requirements of the School of Public Health of their choice. Application forms may be obtained from the Surgeon General, U. S. Public Health Service, Washington 25, D. C. Completed forms, accompanied by two recent photographs and official transcript of college credits and a 500 word statement of why applicant is interested in entering the

field of health education must be in the hands of the Surgeon General by June 1, 1946. Veterans with necessary qualifications are encouraged to apply for fellowship. The subsistence allowance for veterans granted under the G.I. Bill of Rights will be supplemented by fellowship funds to bring the stipend to \$100 a month.

Candidates must maintain a scholastic average of "B" to retain fellowship. Persons accepting fellowships will be expected to work in the field of health education for at least two years after completion of training. The Public Health Service and the National Foundation assume no responsibility for placing fellows in positions.

The Schools of Public Health authorized include those institutions in the United States accredited to give the master's degree in public health as announced in the March issue of the *American Journal of Public Health*: Columbia University, Harvard University, Johns Hopkins University, University of California, University of Michigan, University of Minnesota, University of North Carolina, and Yale University. Candidates will be permitted to express their choice of schools, and efforts will be made to grant first or second choice in so far as possible. The Service has announced that these fellowships are not available to employees of health departments because grant-in-aid funds are available for the training of such personnel.

American Public Health Association

COMMITTEES

1945-1946

IN the April, 1945, issue a complete list of Association Committees, including Section Councils and Representatives to Other Organizations and Committees was published.

The list which follows presents Standing Committees and their Subcommittees, Association Committees, and Representatives. It omits Section Councils because there have been no changes in personnel since the last list was published. It includes only changes in Section Committees. For a complete record of Section Councils and Section Committees for 1945-1946, the listings in the April, 1945, JOURNAL must be used in conjunction with the information provided here.

Subcommittee on Accident Prevention

Donald B. Armstrong, M.D., *Chairman*, One Madison Avenue, New York, N. Y.
 W. W. Bauer, M.D.
 Donald A. Dukelow, M.D.
 Halbert L. Dunn, M.D., Representing Vital Statistics Section
 Thomas Fansler
 F. Ruth Kahl, R.N.

Subcommittee on Reciprocal Sanitary Milk Control

Walter D. Tiedeman, M.C.E., *Chairman*, State Department of Health, Albany, N. Y.
 (Members to be appointed)

Committee on Research and Standards

Kenneth F. Maxcy, M.D., *Chairman*, 615 North Wolfe Street, Baltimore, Md. (1945)
 Reginald M. Atwater, M.D., *Secretary*, 1790 Broadway, New York, N. Y.
 Gaylord W. Anderson, M.D. (1945)
 J. J. Bloomfield (1947)
 Alfred L. Burgdorf, M.D. (1946)
 Halbert L. Dunn, M.D. (1945)
 Haven Emerson, M.D. (1947)
 Gordon M. Fair (1945)
 Thomas Francis, Jr., M.D. (1946)
 James Gibbard (1946)
 Wilton L. Halverson, M.D., *Chairman*, Committee on Administrative Practice (*ex officio*)
 Lucy S. Heathman, M.D. (1946)
 A. Parker Hitchens, M.D. (*ex officio*)
 John F. Norton, Ph.D. (1946)
 Elliott S. Robinson, M.D. (1947)
 Thomas F. Sellers, M.D. (1947)
 Fred W. Tanner, Ph.D. (1947)
 Walter D. Tiedeman, M.C.E. (1945)

Consultant:

Abel Wolman, Dr.Eng.

Subcommittee on Communicable Disease Control

Haven Emerson, M.D., *Chairman*, 600 West 168th Street, New York, N. Y.
 Gaylord W. Anderson, M.D.
 Captain T. J. Carter, M.C., USN
 L. T. Coggeshall, M.D.
 James A. Doull, M.D.
 John E. Gordon, M.D.
 James P. Leake, M.D.
 Kenneth F. Maxcy, M.D.
 Alton S. Pope, M.D.
 George H. Ramsey, M.D.
 Ernest L. Stebbins, M.D.

Subcommittee on Food Utensil Sanitation

Walter D. Tiedeman, M.C.E., *Chairman*, State Department of Health, Albany, N. Y.
 A. W. Fuchs, C.E.
 N. O. Gunderson, M.D.

George J. Hucker, Ph.D.
 Walter L. Mallmann, Ph.D.

Subcommittee on the Hygiene of Housing

C.-E. A. Winslow, Dr.P.H., *Chairman*, 333 Cedar Street, New Haven, Conn.
 Rollo H. Britten, *Secretary*, Federal Public Housing Authority, Washington, D. C.
 Frederick J. Adams
 Charles S. Ascher
 F. Stuart Chapin, Ph.D.
 Henry S. Churchill
 Robert L. Davison
 Clarence W. Farrier
 Alfred H. Fletcher
 L. M. Graves, M.D.
 E. R. Krumbiegel, M.D.
 Bleecker Marquette
 M. Allen Pond
 Mary Rokahr

Abner D. Silverman
Howard P. Vermilya
H. A. Whittaker
Huntington Williams, M.D.
Sidney J. Williams

Staff: 310 Cedar Street, New Haven,
Conn.

Allan A. Twichell, *Technical Secretary*
Anatole Solow, *Research Associate*
Emil T. Tiboni, *Field Secretary*
Rose Olanik, *Assistant Secretary*

Subcommittee on Appraisal of Residential Areas

Rollo H. Britten, *Chairman*, Federal Public
Housing Authority, Washington, D. C.

Subcommittee on Housing Regulation

Charles S. Ascher, *Chairman*, National
Housing Agency, 2 Park Avenue, New
York, N. Y.

Subcommittees on Post-War Standards:

Subcommittee on Environmental Standards

Frederick J. Adams, *Chairman*, Massa-
chusetts Institute of Technology, Cam-
bridge, Mass.

*Subcommittee on Standards for Construc-
tion and Fundamental Equipment*

Henry S. Churchill, *Chairman*, 56 West
45th Street, New York, N. Y.

*Subcommittee on Standards for Space De-
sign and Occupancy*

Clarence W. Farrier, *Chairman*, National
Housing Agency, Washington, D. C.

*Subcommittee on Standards for Installed
Household Equipment*

Mary Rokahr, *Chairman*, War Food Ad-
ministration, Washington, D. C.

*Subcommittee for the Evaluation of
Methods to Control Air-borne Infec-
tions*

James E. Perkins, M.D., *Chairman*, State
Department of Health, Albany, N. Y.
F. Wellington Gilcreas
Alexander D. Langmuir, M.D.
O. H. Robertson, M.D.
William F. Wells
George M. Wheatley, M.D.
C. P. Yaglou

*Subcommittee on Morbidity Registration
and Statistics*

Lowell J. Reed, Ph.D., *Chairman*, Johns
Hopkins University, Baltimore, Md.
Gaylord W. Anderson, M.D.
Edwin L. Crosby, M.D.
W. Thurber Fales, Sc.D.
James P. Leake, M.D.
Franklin H. Top, M.D.
Ellen B. Whiteman

*Subcommittee on the Sixth Revision of
the International List of Causes of
Death*

Edward S. Rogers, M.D., *Chairman*, State
Department of Health, Albany, N. Y.

Committee on Eligibility

Vlado A. Getting, M.D., *Chairman*, 7 Glenn Road, Belmont, Mass.
Reginald M. Atwater, M.D., *Secretary*, 1790 Broadway, New York, N. Y.
Helen Bean, R.N., Public Health Nursing Section (1945)
William R. Davis, D.D.S., Dental Health Section (1946)
Thomas D. Dublin, M.D., Epidemiology Section (1946)
W. Thurber Fales, Sc.D., Vital Statistics Section (1945)
Stanley H. Osborn, M.D., Health Officers Section (1945)
Henry T. Scott, Ph.D., Food and Nutrition Section (1946)
Thomas F. Sellers, M.D., Laboratory Section (1946)
Eunice N. Tyler, Public Health Education Section (1946)
David A. Van der Slice, M.D., School Health Section (1945)
H. A. Whittaker, Engineering Section (1946)
Dorothy Worthington, M.D., Maternal and Child Health Section (1945)
William P. Yant, Industrial Hygiene Section (1945)
Elsie A. Siemer, *Associate Secretary*.

Changes in Section Committees since April, 1945

(Use this information in conjunction with list published in April, 1945, issue)

Laboratory Section

Standard Methods Committee on Examination of Milk and Milk Products

Associate Referee for:

Phosphatase Test — Professor L. H. Burgwald, Ohio State University, Columbus, Ohio, replaces J. H. Shrader, Ph.D.

Engineering Section

Committee on Water Supply

Charles H. Spaulding, replaces Hayse S. Black

Food and Nutrition Section

Committee on Standard Methods for the Microbiological Examination of Foods

Carl S. Pederson, Ph.D., added

Committee on Milk and Dairy Products

Ethel A. Martin, *Chairman*, National Dairy Council, 111 N. Canal Street, Chicago, Ill., replaces J. A. Keenan, Ph.D.

Committee on Foods (Except Milk)

Reginald C. Sherwood, Ph.D., replaces Paul S. Prickett, Ph.D.

Committee on Membership and Fellowship

Alice H. Smith, *Chairman*, Department of Health, Lansing, Mich., replaces Rachael L. Reed

School Health Section

Committee to Study School Health Legislation

N. D. Nielson, Ph.D., added

Public Health Education Section

Committee on Utilization of Commercial Advertising for Health Education

Ann W. Haynes, *Chairman*, 760 Market Street, San Francisco, Calif., replaces Raymond S. Patterson, Ph.D.

Committee on Public Health Education Problems in the Northeastern Region

John E. Farrell, *Chairman*, 106 Francis Street, Providence, R. I.

Membership:

All Fellows and members in the States of the Northeast Region—Maine, Vermont, New Hampshire, Massachusetts, New Jersey, Rhode Island, West Virginia, Maryland, Pennsylvania, New York, Washington, D. C., Connecticut.

Committee on Public Health Education Problems in the Canadian Region

Norman L. Burnette, Sc.D., *Chairman*, 180 Wellington Street, Ottawa, Ont., Canada

Membership:

All Fellows and members in Canada

Committee on Public Health Education Problems in the Hawaiian Region

Alice L. Spillane, *Chairman*, Public Health Fund, Honolulu, T. H.

Membership:

All Fellows and members in Hawaii

Committee on Public Health Education Problems in the Puerto Rican Region

Alice H. Miller, *Chairman*, U. S. Public Health Service, San Juan, Puerto Rico

Membership:

All Fellows and members in Puerto Rico

Representatives of the American Public Health Association to Other Organizations and Committees for 1946

Advisory Council on Medical Education

William P. Shepard, M.D.
James A. Doull, M.D., alternate

American Association for the Advancement of Science

Reginald M. Atwater, M.D.
Abel Wolman, Dr.Eng.

American Committee on Maternal Welfare

Thomas Parran, M.D.

American Documentation Association (1943-1946)

Halbert L. Dunn, M.D.

American Hospital Association (liaison representative)

Charles F. Wilinsky, M.D.

National Committee on Films for Safety

Harry E. Kleinschmidt, M.D.

**National Technological Civil Protection
Committee**

Abel Wolman, Dr.Eng.

Arthur E. Gorman, alternate

Credit Lines

MILWAUKEE LOOKS AT HOUSING

The Association's *Appraisal Method for Measuring the Quality of Housing* has served to dramatize existing slum conditions in Milwaukee and stimulate action regarding them. *The Architectural Forum* for December, 1945, under the title "Slum Slide Rule" says "City health inspectors, armed with new authority to condemn unfit dwellings, made a systematic room to room survey of the city's worst slum area, inspecting and rating by an elaborate point system worked out by the American Public Health Association, every sink, screen door and closet, bed and toilet. . . . First findings showed that spring housecleaning in Milwaukee's sixth ward would be a year-round job."

The same month *The Municipality*, a magazine of municipal affairs of the League of Wisconsin Municipalities, published *An Appraisal Method for Housing Conditions and Needs* by Dr. E. R. Krumbiegel, City Health Commissioner. He points out that the A.P.H.A. *Appraisal Method* is the only mechanism so far developed for an exact analysis of the extent and magnitude of "blighted" areas. He tells in detail the story of how the method is in use in Milwaukee and the way the new municipal ordinance operates in enforcing housing standards.

"Use of the housing appraisal method points the way to housing control on a systematic basis. It renders futile patchwork ordinance of enforcement unnecessary. Community action can proceed on the basis of typical conditions rather than by stressing a few of the worst or best examples of housing in a given area. It becomes possible to report objectively to the municipal administration on the state of housing

in any problem area. The worst slum areas can be demarcated A definite long-range program can then be worked out for these selected areas There are numerous other practical applications of the appraisal method. It is believed that in Milwaukee its use will have effects of primary importance in determining public policy in the fields of housing and city planning."

THE SCHOOL HEALTH SECTION ANALYZES ITS NEEDS

As a new Section of the Association, the School Health Section has utilized the year just past, in which no Annual Meeting was held, to get acquainted with itself, as it were. A recent post card inquiry, answered by nearly 40 per cent of its more than 200 members, and analyzed by S. S. Lifson of the Section's Committee on Pupil Health Experience, reveals a variety of research projects relating to school health being carried on by Section members. Of the 50 studies reported, 25 concerned health service, while others related to health education or college curricula, to in-service training, or to community health education. "These research interests," says the author, "present evidence that those Section members engaged in school health work are not content to look at their responsibilities as routine."

In reply to a request for information as to help desired by members from the Section, the 82 replying listed 63 items on which they would like help. Of these, 27 were requests for information about school health matters—standards for personnel and facilities, definition of school health personnel functions, cooperative experience of departments of health and education, reports on special problems and other bibliographical

material, among them. The next most frequent item for which help was asked was on methods of health education. Others were on case finding methods. Others were on teacher training and in-service training for teachers. Significantly, one request was for action by the Section regarding salary schedules for school health personnel.

Mr. Lifson's detailed analysis of this material is being made available to the membership of the School Health Section.

RURAL HEALTH

Taking cognizance of the fact that "farmers want better health" and that the 57 million rural citizens in the United States do not have parity with urban dwellers in the quality of public health services available to them, the Department of Agriculture's Interbureau Committee on Post-War Problems presents a discussion of the main problems of rural health services and what can be done about them. This is a well illustrated and well printed pamphlet entitled "Better Health for Rural America: Plans for Action for Farm Communities" prepared by a group under the direction of Dr. F. D. Mott of the U. S. Public Health Service, and including Farm Security Administration, Department of Agriculture, Children's Bureau, and Social Security Board personnel.

It summarizes effectively the already known facts about the shortage of doctors, dentists, hospitals and other facilities in rural communities and the adverse effects of poor health services on the rural economy; analyzes what corrective measures have been taken, such as the Department of Agriculture's health programs, development of local health services, Blue Cross plans, and others; and outlines what has to be done now. The current objectives are five: (a) ease the payment of the medical bill, (b) provide adequate hospitals

and health centers, (c) increase the number of doctors, dentists, and nurses in rural areas, (d) organize preventive health services and educate the people about health and disease, (e) elevate the scientific quality of rural medicine and related services. It should have a stimulating effect upon the development of rural health and medical care services.

DENTAL HYGIENISTS IN A DENTAL PROGRAM

Tic, the monthly organ of Ticonium, manufacturers of dental materials and prosthetics, in its issue of February, 1946, initiates "The Dental Hygienists' Corner," a page devoted to the work of the dental hygienist in all fields. Pointing out that dental patient traffic will continue heavy for some time to come, it suggests that the National Association of Dental Hygienists sell the dental hygienist to the dental profession and to the public interested in dental and public health economies. As a medium for this education it reserves a page to be filled by dental hygienists in their individual or association capacities, and pays a \$25 war bond for each contribution in addition. *Tic* already has a "Dental Assistant's Corner."

The February issue also contains a complete reprint of Philip H. Austen's introduction to the 10th edition of *Harris's Principles and Practice of Dentistry*, published in 1879, a year after Austen's death. Its content is significant as an essay on education, particularly of the medical and dental professions.

PSYCHIATRY BELONGS IN GENERAL HOSPITALS

The March, 1946, *Hospital Survey News Letter* of the Commission on hospital care, has an excellent brief review of the trends, dating back to 1729, that led toward broadening the base of general hospital service to give complete

care to all types of patients, including those suffering from mental illness. Among the mile posts mentioned are the Philadelphia and Bellevue almshouses established in 1729 and 1736 to provide custodial care for insane, the admission of mental patients to a special psychiatric division of New York Hospital in 1792, foundation of the American Psychiatric Association in 1844, the psychiatric division of Albany Hospital established in 1902 and, for 1946, "integration of psychiatric services in general hospitals considered practical and desirable."

HEALTH EDUCATION FOR MODERNS

Take-Off by Grace T. Hallock is health education for the air age, prepared for the National Tuberculosis Association. Addressed primarily to high school seniors, it bases its message on the concept of life as a series of take-off and landings—and the preparations necessary for them—the periodic examination, grooming, sportsmanship, fueling, relaxation, safety, responsibility, etc. Each subject is illustrated with an excellent photograph of its airplane counterpart imaginatively assembled and captioned. The pamphlet ends with 11 questions, a "yes" answer to which makes one ready for the "take-off." It is an excellent synthesis of writing, photography, and typography in the service of health.

A NEW SLANT ON GARDENING

The March *Michigan Public Health* is the "Garden Edition," devoted almost exclusively to the home garden, giving detailed instructions for kinds of fruits and vegetables to raise, the varieties suited to the Michigan climate, preparation of soil, time of planting, and amounts to be grown and stored. It is all interestingly written and illustrated, with facts checked by the State Agricultural School or the Department of Agriculture.

And why does a state health department's fancy turn to gardens in the spring? An article in the same issue headed: "Needed: A Cow and a Few Tomato Plants," says, "The urgent need for family gardens is sharply pointed up by recent surveys of foods eaten by school children in two Michigan counties. Children's eating habits showed serious deficiencies in tomatoes, green leafy and yellow vegetables, fruit, and milk." Another article reminds the reader that "world food shortages are critical." And finally in an article "Gardens for Health," Dr. DeKleine, the Health Commissioner says, "Yes! There is an abundance of wealth in gardening if we measure the dividends in physical, mental, and spiritual values."

This issue seems to Credit Lines a unique and imaginative tying up of parochial and world interests, and finding the recreative values in useful projects.

HEALTH PROJECTS IN LATIN AMERICA

The Food Supply Division of the Institute of Inter-American Affairs publishes a monthly report which should be of value to persons who are interested in Latin American health projects. The report is generously illustrated with native people and scenery and contains a good brief summary of health activities being carried on in various Central and South American countries.

The Health and Sanitation Division likewise issues a fortnightly newsletter giving sanitation news of the Americas.

UNITED NATIONS NEWS

The January, 1946, issue of *United Nation News* is Vol. 1, No. 1, published monthly by the Woodrow Wilson Foundation and devoted exclusively to news and reports about the meetings of the U.N., its functional agencies and other international organizations. Its aim is to meet the need for information in compact form about the many

international organizations in which Americans have assumed responsibility.

THE TOLL OF ACCIDENTS

The *United States Municipal News*, published weekly by the U. S. Conference of Mayors, on March 1 showed some National Safety Council figures comparing the number of war and accident casualties from Pearl Harbor to V-J Day. Killed in war were 261,608 persons, in home front accidents, 355,000; wounded in war, 651,911, and injured in home front accidents, 36,000,000. The figures, it is said, are presented to emphasize the importance of preventing accidents, not to imply that the fighting front is less dangerous than the home front.

SAYING IT WITH PICTURES

The January *News Letter* of the Kansas State Department of Health reproduces a cartoon used on school dental inspection forms, the gist of which is, "Your mouth is your constant servant; take good care of it." A good illustration of the effectiveness that can be achieved with simple line drawings.

ANNUAL REPORTS

Metropolitan Health Council (Columbus, Ohio)—A comprehensive summary of a year's doings of an active local health council. One section "A Look into 1946," quotes three of the recommendations of the Gunn-Platt report with the comment that they "should challenge the best thinking of all interested groups." There is also a short report of each of 9 committees. A directory of health services and another of clinics accompany the report.

Making Health Visible—Both the annual and the nine year report of the Cleveland Health Museum which effectively summarizes the first nine years of this unique museum. The development of extension services, of the internship system, and of the expanding

influence of the Museum are all illustrated verbally and pictorially. This report punctuates the end of an era for the Museum; in the spring of 1946 it will move into a new and enlarged building with facilities for broader usefulness.

TUBERCULOSIS HEALTH EDUCATION

The Tuberculosis Institute of Chicago and Cook County, which is a local organization of the National Tuberculosis Association, sends Credit Lines its recently prepared *Community Forum and Exhibit on Tuberculosis*. Inspired in part by the problem of the returning tuberculous veteran and the difficulty of keeping him under care, this pamphlet outlines a complete program of health education and a health exhibit, giving not only the philosophy behind the program and the needs which it is aimed to meet, but also outlines procedures to be followed in organizing the community, objectives to be met, methods to be employed, content of program, exhibit, and evaluation. All this is done, not by way of theory, but by describing the forum and exhibit and the continuing organization in Cook County under 9 subcommittees.

ALCOHOLIC A PUBLIC HEALTH PROBLEM

Two recent items indicate the growing awareness of the alcoholic as a public health problem. The first is a three day institute in chronic alcoholism held in February, 1946, at the University of Minnesota Center for Continuation Study. The faculty of 12 included 6 physicians, among them Dr. Haven Emerson. Others included E. M. Jellinek, Director of the Yale University School of Alcohol Studies, judges and probation officers. Among the topics discussed were the pharmacology and sociology of alcohol, the clinical and psychiatric manifestations of alcoholism, its legal aspects and its social treatment.

The second item is the February, 1946, *Timely Health Topics*, the Bulletin of the Fort Worth-Tarrant County Health Education Committee (Texas), which is devoted entirely to a discussion of alcohol, alcoholism and the alcoholic, and some of the plans for his rehabilitation.

BOSTON'S HEALTH UNITS

The expanding interest in health centers across the country will provide a welcome for the newly published review of Boston's Health Units, established from the income of the George Robert White Fund. This booklet describes the buildings and their program and gives the reader a comprehensive idea of the project now almost thirty years old.

Charles F. Wilinsky, M.D., the Deputy Commissioner of Health in charge of health units, and the person whose continued interest has made possible these outstanding health centers in Boston, points out the origin of the project with the opening of the Blossom Street Health Unit in 1916. "In the light of the present belief as to the importance of the health center as a focal and central point for the conduct of health and welfare work on a district level, and in view of the rapid expansion of this development, it may be safely assumed that the planned objectives of almost thirty years ago have in a marked degree been realized. Believing that the seven Health Units, built and equipped by the George Robert White Fund at a cost of approximately three million dollars, are of interest to public health and welfare leaders, it has been decided to bring up to date and to republish this booklet first printed a decade ago. We hope that this description of our health units, how they were established, and the activities carried on, will be of interest and value to its readers."

Public health planners are indebted

to Boston for making this excellent report available. It is highly recommended reading.

25 YEARS OF PUBLIC HEALTH IN CHARLESTON, S. C.

The Charleston (S. C.) County Health Department has recently published a history of its first quarter of a century. Well printed on good paper and extensively illustrated with photographs and charts it is a meaningful record of achievement.

Actually this health department has a much longer history. Although the County Health Department is only 25 years old, Charleston City, whose health work was incorporated in the County Unit ten years ago, had a board of health as early as 1796.

The County Health Department was set up in 1920 following a Public Health Demonstration sponsored by the State Board of Health and the U. S. Public Health Service, and received early financial support from the Rockefeller Foundation. In 1926, the present Health Officer, Dr. Leon Banov, who had served the city department in various capacities since 1913, administered both the city and county units; in 1927 both health units were located under one roof, and in 1936, says the historical report, "It was realized that health problems did not stop at the city limits and that the City and County Health Departments had a common purpose—making a safer, cleaner, healthier, and happier county—and at a great financial saving to the citizens, the two departments merged into the Charleston County Health Department."

Charleston County won honorable mention in the National Health Conservation Contest in all the years between 1932 and 1936 and in 1939, winning first place in 1938.

HOME SAFETY—A CINCINNATI PROGRAM
Bleecker Marquette sends the follow-

ing story of a home safety educational program organized for the Public Health Federation of Cincinnati by its President, William S. Groom, who is using his experience as an advertising expert to serve as a volunteer health educator on the Federation staff.

"The subject of home accidents presents unusual problems, particularly with respect to a practical and effective means of reaching into all the homes with an educational program.

"In industry, employees are gathered together every working day where they can be readily subjected to a continuing program of accident prevention. Accident hazards can be scientifically studied and mechanical safeguards installed. Working habits of employees can be supervised and safety rules taught and enforced.

"In the case of traffic accidents, drivers of motor vehicles are registered. They can be taught and tested where state laws permit. They can be reached through motor clubs or through their employers if they drive commercial vehicles. They are also subject to supervision and enforcement through the medium of the traffic laws.

"No similar means exist for attacking the problem of accident hazards in the home, where physical conditions and human habits and attitudes cannot readily be studied, supervised or controlled.

"The problem of home accident prevention is made more difficult also because people generally recognize the inherent danger of accidents in industry and traffic but believe that "home is the safest place in the world."

"A further difficulty arises from the fact that elderly people are involved in a high percentage of all fatal accidents in homes and they are not easily influenced or changed in their habits and attitudes.

"Many communities have well organized programs for the control of indus-

trial and traffic accidents, but in view of the greater difficulties in approach to the problem of home accidents it is not surprising that few if any communities have similarly well organized programs in this field.
